About the Author

Srikanth Pragada is the director of Srikanth Technologies, a software training company. He started programming in early 90s and worked with more than 15 different programming languages.

Sun Certified Java Programmer
Sun Certified Web Component Developer
Sun Certified Business Component Developer
Oracle Database SQL Certified Expert
Oracle PL/SQL Developer Certified Associate
Microsoft Certified Technology Specialist for .NET 4.0
(Web Applications)

Srikanth Pragada holds the following certifications:

He currently conducts online, classroom and onsite training on C, Java, Java EE, Hibernate, Spring, Oracle, Microsoft.NET, Python, Django, Data Science, AWS, Angular and React.

His website <u>www.srikanthtechnologies.com</u> contains online examinations, programs, projects and his blog.

When he is not teaching or learning, he would like to visit new places, read books, involve in sports and listen to music.

He can be reached through his email address srikanthpragada@gmail.com.

How to use this material

You are suggested to read relevant content before and after attending the class.

Use picture and text to grasp the concept. Programs are to illustrate how to implement the concepts. Try the programs given in this material in your system.

Answers for exercises given in this material are found at http://www.srikanthtechnologies.com/books/javabook2021/answers.html

Programs discussed in this material can be found at: https://github.com/srikanthpragada/JavaSE Material 2021 Programs

Request for Feedback

We have taken considerable effort to ensure accuracy of the contents of this material. However, if you come across any mistakes or have any suggestions to improve the quality of this material, please take a few minutes of your valuable time to send mail to me at **srikanthpragada@gmail.com**.

Alternatively, you can visit my website http://www.srikanthtechnologies.com/feedback.aspx and provide feedback there.

Getting Started

What is Java? □ A general-purpose programming language. □ Invented by James Gosling, Patrick Naughton, Chris Warth, Ed Frank and Mike Sheridan at Sun Microsystems. □ Java was released in May, 1995. □ Most widely used programming language. □ Mainly used to develop web and enterprise applications. □ Provides "write once and run anywhere" features – Platform independence. □ Influenced by C and C++. □ Derives its syntax from C and C++. However, it eliminated features of C++ such as multiple inheritance, operator overloading, friend function etc. that could cause ambiguity. History of Java The following are some important versions of Java, when they were released and what features were added.

☐ Java 1.0 was released in May, 1995. Java was initially called as "oak" and then

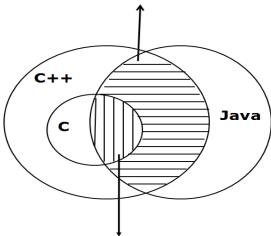

Editions of Java

Java is provided as three different editions, where each edition is meant for different types of applications. Java Standard Edition – Java SE ☐ Java Enterprise Edition – Java EE Java SE (Standard Edition) ☐ This is used to develop Console applications, Applets and Frame-based applications (desktop applications). ☐ This edition provides features of language, core API (Application Program Interface) related to IO Stream, Networking, Data structures using Collections Framework etc. This edition comes with Java compiler, JVM and other tools to develop applets and desktop applications. Java EE (Enterprise Edition) ☐ This is used to develop web applications, web services, and enterprise applications. It uses Java Language and core API. ☐ It is a set of specifications to be implemented by products. BEA's WebLogic server, IBM's WebSphere, Open-source product JBoss, Glassfish etc. implement Java EE specifications. Major topics of Java EE are Servlets, JSPs, Enterprise Java Beans (EJB), JavaServer Faces (JSF).

Relationship between C, C++ and Java

- ☐ C was released in 1970. C++ was released in 1980. Java was released in 1995.
- ☐ C and C++ are meant for System programming whereas Java is meant for application programming.
- ☐ Java uses control structures such as if, for etc. of C language.
- ☐ Java does not support pointers, pointer arithmetic and unions.
- ☐ Java and C++ have OOP (Object Oriented Programming) as common feature.
- ☐ However, Java has ignored a lot of features of C++ as these features would cause ambiguity.
- □ Default function arguments, Operator overloading, Multiple inheritance, Friend functions etc. of C++ are not supported by Java.
- ☐ C and C++ concentrated more on providing flexibility and power, but Java's main focus has been robustness and Internet programming.

Common Features of C++ and Java

Common Features of C and Java

Features of Java Language

The following are the major features of Java language.

Robust	Makes programs robust (free from potential errors). Java detects all potential problems at the time of compiling the program. It also checks for array boundary violation etc. at run time.
Object Oriented	Supports encapsulation, inheritance and polymorphism. Java allows the entire code to be placed only in classes. It doesn't allow any code to be placed outside the class including main() method.
Dynamic	Allocates memory for arrays and objects at run time and handles allocation and de-allocation of memory on its own. Garbage collector is responsible for releasing unused memory blocks.
Multithreaded	Supports creating and managing of multiple threads.
Distributed	Supports programs to run on different systems and yet communicate with each other. Provides mechanism to transmit data from one application to another.
Platform Independent	Allows a compiled program (byte code) to run on any other platform.

18

Java is Robust

- ☐ Java, being a robust language, checks for potential errors both at the time of compilation and at runtime.
- ☐ Java is strongly typed language, where data type of a value cannot be changed to another, and is case-sensitive.
- ☐ The following snippets show operations that are allowed in **C** but not in **Java**.

```
01: int a[10];
02: int i, j;  // local variables, not initialized
03: a[10] = 100;  // accessing element outside the bounds
04: i = 10.50;  // assigning float to int
05: j++;  // using without initializing it
```

☐ Java also checks whether a function that is supposed to return a value is really returning a value.

```
01: /* This function does not compile as it does not
02: return value when condition is false. */
03: int fun(int v) {
04:   if (v > 10)
05:     return 1;
06: }
```

☐ Java checks whether a piece of code is reachable during the execution of program. If code is not reachable in all paths of execution, then it complains about it.

```
01: /* Unreachable code example */
02: int fun(int v) {
03:    if (v > 10)
04:        return 1;
05:    else
06:        return 0;
07:
08:    v ++ ; // cannot be reached.
09: }
```

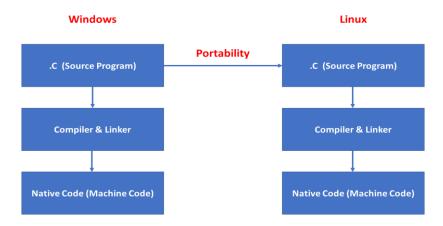

Platform Independent Language

The main feature of Java language is its **platform independence**. This allows a Java program that is compiled on one platform to run on any other platform.

This is called as WORA (Write Once, Run Anywhere).

Platform independence is different from Portability.

Portability allows source code to be ported to different platforms. Though source program is ported we need to compile the source program on the target platform before running it.

All high-level languages have portability.

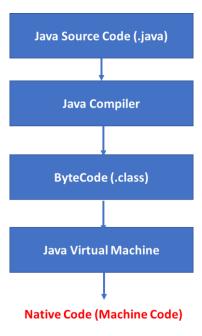

Native code is the code understood by the Microprocessor and operating system of the computer.

NOTE: Platform is the environment in which application programs run. It is typically the combination of operating system and the hardware. Platform is generally synonymous with operating system.

Compiling and running of Java Program

The following figure shows the steps related to compiling and running of Java program. Java programs are NOT compiled to native code and instead they are compiled to **Bytecode**, which is close to native code but not native code of any platform.

Once a Java program is compiled to bytecode then it can be run on any platform where JVM (Java Virtual Machine) is available.

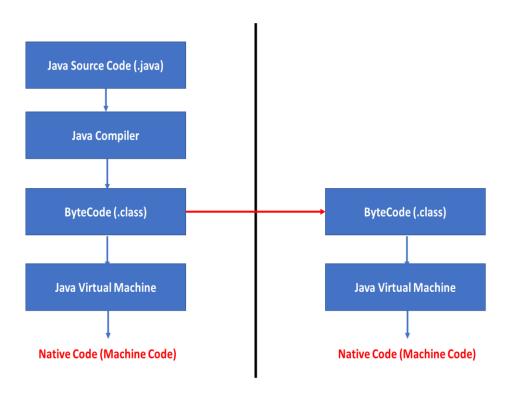

NOTE: Java compiler and JVM are specific to each platform. Only bytecode is platform independent.

Java and Platform Independence

The following picture shows how a Java program that is compiled on Windows system can run on Linux system.

Once a Java program is compiled to Bytecode (.class file), it can be executed on any machine where JVM is available.

Most of the modern operating systems provide JVM along with operating system allowing byte code to run straight away.

Using Java SE

- □ Download Java SE (a.k.a. JDK Java Development Kit) from https://www.oracle.com/in/java/technologies/javase-downloads.html
- ☐ Installing Java SE is as simple as double clicking on downloaded file (.exe file) and following the steps.
- ☐ It is better you install Java SE into a directory like **c:\jdk**, instead of the default directory (which is **program files** directory).

Directory Structure of Java SE

After you install Java SE into a directory (say c:\jdk), the structure of the directory will look like below:

```
c:\jdk
bin
javac.exe, java.exe
include
lib
*.jar
conf
*.properties
```

Directory	Description
bin	Contains executable files related to JDK. It contains JAVAC.EXE and IAVA.EXE.
include	Includes files for Java Native Interface.
lib	Contains Java libraries, which are in the form of .jar (Java archive)
	files.
conf	Contains configuration files.

Basic Tools

These tools are the foundation of the JDK. They are the tools you use to create and build applications.

Tool Name	Brief Description
Javac	The compiler for the Java programming language.
Java	The launcher for Java applications (JVM).
Javadoc	API documentation generator.
Jar	Create and manage Java Archive (JAR) files.
Jdb	The Java Debugger.

First Java Program – Hello.java

The following is the smallest possible Java program.

```
01: // Program to print Hello World
02: public class Hello {
03:    public static void main(String args[]) {
04:        System.out.println("Hello World!");
05:    }
06: }
```

The above Java program prints message Hello World!, when you compile and run it.

The following are some of the important components of this program.

- Every function in Java must be inside a class, so we have to create class Hello to put main() function in it.
 Function main() must be declared as static. It must return nothing (void) and it
- takes an array of type **String** as argument. All these are mandatory. **System.out.println()** is used to print the given message.

Compiling and running a Java program

To compile a java program using JDK, follow the steps given below:

1. Go to command prompt using programs \rightarrow accessories \rightarrow command prompt.

2. Set **PATH** command of Windows to **bin** directory of **jdk** as follows at the command line.

path c:\jdk\bin

PATH is required as *javac.exe* and *java.exe* are in bin directory.

- 3. Go to directory where **Hello.java** is saved (c:\jdk\programs).
- 4. Compile Java program using JAVAC.EXE as follows:

javac Hello.java

5. Run java program as follows from the command line:

java Hello

NOTE: PATH command is used to inform Operating System (Windows) where it should search in the file system for executable files. By default, OS searches for executable files only in current directory. To see the current PATH setting, just type PATH at the command prompt.

The following screenshot shows how to set path, compile Java program and run it using JVM, assuming the program Hello.java is in folder srikanth.

```
C:\jdk\srikanth\path c:\jdk\bin
C:\jdk\srikanth\javac Hello.java
C:\jdk\srikanth\java Hello
Hello World!
C:\jdk\srikanth\_
```

Using IDE

It is strongly recommended you use IDE to write Java code.

IDE (Integrated Development Environment) provides a lot of features to make developers more productive.

Eclipse, NetBeans, IntelliJ IDE are some of the most widely used IDEs for Java.

Check my video tutorial <u>Getting Started with Eclipse IDE for Java Developers</u>.

Standard or Primitive data types in Java

The table below shows the list of data types available in Java along with number of bytes occupied by the data type and range of values that can be stored in the data type.

Data Type	Size (Bytes)	Range
byte	1	-128 to 127
short	2	-32768 to 32767
int	4	-2147483648 to 2147483647
long	8	-9223372036854775808 to 9223372036854775807
float	4	3.4e-038 to 3.4e+038
double	8	1.7e-308 to 1.7e+308
boolean		true or false
char	2	Supports Unicode characters

All numeric types in Java are signed.
 The size of boolean is JVM dependent.
 Data type char occupies two bytes because it supports Unicode, which needs 16 bits to store characters.
 Unicode supports characters of all languages and some languages of Japanese and Chinese have more than 256 characters.
 The size of data types does NOT change from platform to platform.

NOTE: Java doesn't allow an un-initialized variable to be used. By default, local variables are not initialized by Java.

Rules to create Identifier

A name in the program is called as identifier. The following rules are to be followed while creating identifier.

Can contain letters, digits, _ (underscore) and \$.
 Must NOT begin with a number. Can start with currency symbol (\$) or _ (underscore).

☐ Keywords of Java cannot be used.

Valid identifiers	first_number, name\$, _first, \$amount
Invalid identifiers	2num, total-amount

Keywords in Java

The following is the list of Java keywords. All these keywords are in lowercase.

abstract	continue	for	new	switch
assert	default	goto	package	synchronized
boolean	do	if	private	this
break	double	implements	protected	throw
byte	else	import	public	throws
case	enum	instanceof	return	transient
catch	extends	int	short	try
char	final	interface	static	void
class	finally	long	strictfp	volatile
const [.]	float	native	super	while

true and false are boolean literal

☐ null is null literal

var, yield, and record are restricted identifiers

Literals

Literal denotes a constant value, which remains unchanged throughout the program.

Java has three reserved literals – null, true, false.
Integer literals are treated as integers unless they are suffixed with L (letter L).
Example: 100L
Java 7.0 onwards we can use _ (underscore) as separator between digits.
Integer literals can be specified in octal (0123) or hexadecimal (oxff). Octal
numbers are prefixed with 0 and hexadecimal numbers are prefixed with 0x .
Floating point literals are by default taken as double . Use suffix f to denote
float literal. Example, 10.50f.
Starting from Java 7.0, we can have binary literals prefixed with 0b .
Escape sequence as well as Unicode values can appear in string literals. For
example, "How are you\t Srikanth\u000d" represents a string that contains a
horizontal tab (\t) and carriage return (\u000d in hexadecimal is equal to
decimal 13).

Integer	200 -7 1_23_456 0b10001111
Floating point	2.4 -2.5 .5 0.55
Character	'a' '9' ':'
Boolean	true false
String	"one" "123" "work hard"

Escape Sequence Characters

The following are the escape sequence letters supported by Java.

Character	Meaning
\ddd	Three octal digits
\uxxxx	Four hexadecimal digits
\'	Single quote
\"	Double quote
\\	Single backslash
\r	Carriage return
\n	New line (also known as line feed)
\f	Form feed
\t	Tab
\b	Backspace

Text Blocks

- ☐ A text block is enclosed in """ (three double-quotes) and """ and can contain multiple lines and quotes.
- ☐ Special escape sequence \s inserts space and \ suppresses new line.

```
String text = """
First Line
\s\sSecond Line \
is here!
\s\sThird Line
""";
System.out.println(text);
```

```
First Line
Second Line is here!
Third Line
```

Operators in Java

An operator performs specific operation on the given value(s) called as operands. Operators are divided into different categories based on the operation performed by the operator.

Arithmetic Operators

The following table shows arithmetic operators available in Java. They are shown according to the precedence of the operators.

Operator	Meaning
++	Increment
	Decrement
*	Multiplication
/	Division
%	Modulus
+	Addition
-	Subtraction

Associativity specifies whether operators are grouped from left to right or right to left. Unary ++ and — operators are having **right to left** associativity and other operators are having **left to right** associativity.

Conversion and Type Casting

- ☐ Java allows assignment between variables of compatible types.
- ☐ Java promotes all integer types such as **byte** and **short** to **int**.
- ☐ When we are converting a large data type to short data type, explicit **type** casting is required.

```
// will FAIL as 10.50 is taken as double
float f = 10.50;

// Use f as suffix to indicate float
float f = 10.50f;

// converts double to float and then assigns
float f = (float) 10.50;
```

Assignment Operator

Assignment operator (=) is used to assign a value to a variable. The value may be either a literal or an expression.

The variable and result of the expression must be of compatible data types. Java also supports multiple assignments, where you can assign a single value to multiple variables in a single assignment.

```
a = 0;
a = b = c = 0;
```

Relational Operators

- ☐ All relational operators are binary operators.
- ☐ The result of the evaluation is always a boolean.
- ☐ Relational operators have *left to right associativity*.

Operator	Meaning
==	Equal To
>	Greater than
<	Less than
<=	Less than or equal to
>=	Greater than or equal to
!=	Not Equal To

Logical Operators and Short-circuiting

Logical operators combine two conditions and return a boolean value. The following table shows logical operators.

Operator	Meaning
&	AND
	OR
٨	XOR (exclusive or)
	Short-circuit OR
&&	Short-circuit AND
!	Unary NOT

Short-circuit Logical Operators (&& and ||)

Short-circuit operators check only the necessary conditions and do NOT check both the conditions always. Evaluation of condition stops once the outcome of the condition is known.

&&	Doesn't check second condition if first condition is false.
	Doesn't check second condition if first condition is true.

if
$$(a > b \& a > c) ...$$

Returns false if condition $\mathbf{a} > \mathbf{b}$ is false and doesn't check second condition ($\mathbf{a} > \mathbf{c}$).

Returns true if condition a == b is true and doesn't check second condition.

Bitwise Operators

Bitwise operators operate bits in integer. They can be used only with integer data types such as int and long.

Operator	Meaning
~	Ones complement
&	Bitwise Anding
1	Bitwise Oring
٨	Bitwise XOR (Exclusive OR)
<<	Shifts bits to left by n times by filling 0 on the right
>>	Shifts all bits right by n times, filling left side bits with sign bit
>>>	Shifts all bits right by n times, filling left side bits with 0

The following snippet shows how to use bitwise operators.

```
public class BitOperators {
01:
      public static void main(String[] args) {
02:
03:
        byte a = 10, b = 15;
                         0000 1111 = 0000 1010
04:
        // 0000 1010 &
05:
        System.out.printf("%d
                                & %d = %d\n", a, b, a & b);
06:
        // 0000 1010
                         0000 1111
                                        0000 1111
                                     =
        System.out.printf("%d
                                | %d = %d n", a, b, a | b);
07:
       // 0000 1010 >> 2
08:
                                        0000 0010
        System.out.printf("%d \Rightarrow 2 = %d\n", a, a \Rightarrow 2);
09:
10:
        // 0000 1010
                      << 2
                                     = 0010 1000
        System.out.printf("%d << 2 = %d\n", a, a << 2);
11:
12:
      }
13: }
```

Control Statements

The following are conditional statements and looping structures available in Java.

if statement

The **if** statement is used to decide whether an operation is to be performed. If **condition** is true then statement-1 is executed, otherwise statement-2 is executed. The **else** portion is optional.

```
if (condition)
    statement-1;
[else
    statement-2;]
```

NOTE: If multiple statements are to be executed then enclose statements in braces ({}).

It is possible to have nested if statements (an if statement within another if statement). It is also possible to have multiple if statements with if .. else.. if .. else and so on.

switch statement

The switch statement is used to execute one among many alternatives.

```
switch(expression)
{
  case label-1 : statement; [break];
  [case label-2 : statement; [break];]...
  [default : statement; ]
}
```

The following example takes same action for code 1 and 2 and different action for 3, and default is used to take action for the rest of the codes.

```
switch(code) {
  case 1 : // falls through to next case
  case 2 : price = 1000; break;
  case 3 : price = 500; break;
  default: price = 100;
}
```

For switch statement, the expression must be a **char**, **byte**, **short**, **int** or an **enum** type.

Starting from Java 7.0, switch supports string data type also.

```
String country;
// code to get value into country
switch(country)
{
   case "India": // code
   case "China": // code
   case "Japan": // code
   default: // code
}
```

The case constant must evaluate to the same type as the expression. The case constant must be a compile time constant.

NOTE: The default case doesn't have to come only at the end of the switch statement; it can be given anywhere.

The switch expression

- ☐ A switch expression, introduced in Java 12, returns a value.
- ☐ Unlike switch statement, switch expression returns a value for each case using operator ->.
- ☐ To return a value from a block of statements, we can use yield statement from Java 13.
- ☐ Switch expression also supports multiple labels for a single case.

The syntax for **case** changes in switch expression as follows:

```
case label_1, label_2,..., label_n ->
    expression; | throw-statement; | block
```

The following switch returns discount rate based on product code:

```
int disrate =
    switch (code) {
        case 1 -> 10;
        case 2 -> 20;
        case 3 -> 25;
        default -> 5;
    };
```

Multiple labels

It is possible to use multiple labels for each case by separating them using comma (,).

The following switch expression returns number of days based on value of month. It uses multiple values for case.

```
int days = switch (month) {
    case 2 -> 28;
    case 4, 6, 9, 11 -> 30;
    default -> 31;
};
```

Using yield in switch

It is possible to use **yield** to return a value when a case has a set of statements (block).

The following example demonstrates how to use yield in a case when it is not possible to return value with -> alone.

```
int days = switch (month) {
  case 2 -> {
    if (year % 4 == 0 && year % 100 != 0 || year % 400 == 0)
        yield 29;
    else
        yield 28;
    }
  case 4, 6, 9, 11 -> 30;
        default -> 31;
};
```

The while loop

Repeatedly executes statement(s) as long as the condition is true.

```
while(condition)
statements;
```

Following example displays all numbers from 1 to 10. To execute multiple statements, enclose statements in braces ({}).

```
int i = 1;
while (i <= 10) {
    System.out.println(i);
    i ++;
}</pre>
```

The do .. while loop

Executes the body of the loop and then checks the condition thus guaranteeing the execution of the statement *at least for once*.

```
do {
   statement;
} while (condition);
```

The following program displays numbers from 1 to 10.

```
int i = 1;
do {
    System.out.println(i);
    i ++;
} while (i <= 10);</pre>
```

The for loop

The **for** loop executes statements as long as the condition is true. First it executes initialization, then checks whether condition is true. If condition is true then executes the statements and then increment portion.

```
for (initialization; condition; increment)
    Statement;
```

Variable can be declared within initialization and these variables are available only within the loop.

```
// Variable i is available only within for
for (int i = 1; i <= 10; i ++) {
    // body
}</pre>
```

The break statement

The **break** statement is used to terminate loop from inside the loop. Java provides labeled break and unlabeled break. When break statement is used without any label, it terminates current loop.

break [label]

Labeled break terminates the loop that is associated with the given label. In the following example, break terminates 1st loop as label first is associated with i loop.

```
01: first:
02: for(int i = 0; ...){
03:
      second:
      for(int j = 0; ...) {
04:
          for(int k = 0; ...) {
05:
             if (cond)
06:
                break first;
07:
          }
08:
09:
     }
10:
```

The continue statement

Continue is used to stop the current iteration of the loop body and proceed with the next iteration.

continue [label]

The following code ignores remaining statements in **j** loop when condition is satisfied and starts next iteration.

Printing value using System.out.printf()

Function printf() is similar to printf() function of C language. The following are the conversion characters that can be used.

b - boolean, **c** - char, **d** - integer, **f** - floating point, **s** - string.

```
System.out.printf("int %d and float %f \n", i, f);
```

If conversion character and given data do not match then a runtime error occurs. The following will produce a runtime error.

```
System.out.printf("%d",10.50);
```

46

Reading input using Scanner

Input from users can be taken using Scanner class. The following snippet shows how to use Scanner to read an integer from user.

```
Scanner s = new Scanner(System.in);
int n = s.nextInt();
```

The following program reads a number from user using Scanner and displays its factors.

```
01: import java.util.Scanner;
02:
03: public class Factors {
      public static void main(String[] args) {
04:
          Scanner s = new Scanner(System.in);
05:
          System.out.print("Enter a number :");
06:
          //read an int from keyboard
07:
          int num = s.nextInt();
08:
09:
          for(int i = 2; i <= num/2; i ++) {
10:
              if(num % i == 0)
11:
12:
                  System.out.println(i);
13:
      }
14:
15: }
```

The **import** statement is required to make **Scanner** available to current program.

Method	Description
nextInt()	Reads next integer
nextDouble()	Reads next double
nextLine()	Reads next line and returns as a string

47

Creating and using Arrays

- ☐ Array is a collection of elements.
- ☐ All elements of the array are of the same type.
- ☐ All elements are commonly referred by a single name and individual elements are accessed using index.
- ☐ An array in Java is dynamic. We specify the size of the array at runtime.

```
int a1[];  //declare an array
int []a2;  //another syntax to declare an array

// Create an array of 10 elements
a1 = new int[10];
```

Alternatively, you can declare and allocate memory in one step.

```
// Declare and create an array
int a1[] = new int[10];

/* create an array where size of the array is determined by
the value of variable n */
int a2[] = new int[n];
```

Getting array's length using length property

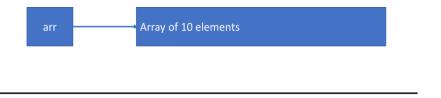

Property length of an array can be used to get number of elements in an array.

```
System.out.printf("Length: %d", a.length);
```

An array name can be used to refer to an array of different sizes at runtime. The following snippet shows how array name **arr** points to an array of 10 elements first and then points to an array of 5 elements.

```
// create an array
int arr[] = new int[10];

//Array arr points to a new array of 5 elements
arr = new int[5];
```

Old array of 10 elements referred by **arr** is now eligible for garbage collection by Java.

NOTE: Java virtual machine has garbage collector, which takes care of releasing unused memory blocks.

You can create a double dimensional array using two square brackets as follows:

Enhanced for loop

Java provides enhanced for loop exclusively to process arrays and collections. It takes one value from array and assigns it to loop variable. Executes loop statements and repeats the process until array is exhausted.

```
for (datatype loopvariable : array)
Statement;
```

The following example displays all elements of an array using enhanced for loop. The data type of loop variable and data type of the array must be same.

```
int a [] = {10,20,30,40,50};
for (int n : a)
   System.out.println(n);
```

Initializing an array

Java allows an array to be initialized. The following examples show how you can initialize an array in Java.

```
// initializes array a to given three values
int a[] = {10,20,30};

// initializes array b to given five values
int b[] = new int[] {10,20,30,40,50};

// initializes double dimensional array - 2 X 3
int bb[][]= {{1,2,3},{4,5,6}};
```

NOTE: Elements of an array are automatically initialized to default value according to data type of array.

Variable Number of Arguments

- ☐ Java allows a method to take variable number of arguments.
- ☐ The argument is declared with ... (ellipses) after data type and before the name.
- ☐ Must be the last argument in a method.
- ☐ Argument is treated as an array inside the method.

```
public class VaryingArguments {
01:
       public static void main(String[] args) {
02:
03:
           System.out.println(getSum(10, 20, 30));
           System.out.println(getSum(100, 200));
04:
05:
       public static int getSum(int... nums) {
06:
07:
           int total = 0;
           for (int n : nums) {
08:
               total += n;
09:
10:
           return total;
11:
12:
       }
13: }
```

Command-line Parameters

- ☐ Parameters that are passed at the time of invoking a java program from command line are called as command line parameters.
- ☐ These parameters can be used to provide input to the program.
- ☐ These parameters are accessible from *main()* through *args* parameter, which is an array of strings.
- ☐ The *length* attribute of *args* returns the number of parameters passed on command line.

```
01: // program to display command-line parameters
02: public class CLA {
03:  public static void main(String args[]) {
04:    System.out.printf("Args Count: %d\n", args.length);
05:    // display parameters
06:    for(String s : args)
07:        System.out.println(s);
08:    } // end of main
09: }
```

Call the previous program from command line as shown below:

```
c:\jdk\srikanth>java CLA One Two <Enter>
Args Count : 2
One
Two
```

52

NOTE: Method main() must have a parameter of type String[]. However, the name of this parameter could be anything. The following code is same as code above.

Program - Prime.java

This program checks whether the number given on the command line is a prime number or not. Prime number is a number which has no factors other than 1 and itself

```
01: // program to check whether a number is prime
02: public class Prime {
       public static void main(String[] args) {
03:
            // check whether number is passed
04:
            if (args.length == 0) {
05:
               System.out.println("Number is missing!");
06:
07:
               return;
08:
            }
            // convert args[0] to int
09:
            int n = Integer.parseInt(args[0]);
10:
            boolean prime = true;
11:
12:
            for (int i = 2; i <= n/2; i ++) {
13:
              if (n \% i == 0) {
14:
                 prime = false;
15:
16:
                 break;
17:
            } // end of for
18:
19:
            if (prime)
20:
              System.out.println("Prime Number");
21:
22:
            else
              System.out.println("Not a prime number");
23:
       } // end of main
24:
25:
```

Prime program does the following:

- 1. It checks whether command line argument is given. If not, it terminates main() by using return statement.
- 2. Converts first command line argument to an int.
- 3. Sets a loop that runs from 2 to n/2.
- 4. If a number in the range 2 to n/2 can divide the number without any remainder then it breaks the loop after setting prime variable to false.
- 5. If no number in the range 2 to n/2 can divide number without any reminder then loop terminates but prime variable's value remains true.
- 6. At the end it displays a message based on the value of prime variable.

Run this program with a number on command line as shown below:

C:\jdk\srikanth>java Prime 23 <enter>
Prime Number

Exercises

Try to write programs to accomplish the following tasks.

- 1. Display first 10 Fibonacci numbers.
- 2. Display all palindrome numbers in the range 1000 to 2000.
- 3. Write a program to take a number from user and display whether it is a perfect number.
- 4. Accept ten numbers from user and display the largest of the given numbers.
- 5. Accept two numbers and display the GCD of the numbers.
- 6. Accept two numbers on command line and raise base (first number) to power (second number).
- 7. Accept a number and display its highest factor.
- 8. Accept a number and display the digits in reverse order.
- 9. Create a function that takes a set of integers using varying length argument and returns the average of all the numbers.
- 10. Create an array of 10 elements. Read values from keyboard and fill the array. Interchange first 5 elements with last 5 elements and display the array.

NOTE: Find answers for these exercises at

http://www.srikanthtechnologies.com/books/javabook2021/answers.html

Object Oriented Programming Part - 1

Object Oriented Programming

- ☐ Java is an object-oriented programming language. So, it is important to understand what object-oriented programming is.
- OOP allows program to be divided into objects, where each object contains data and code to process data.
- ☐ These objects of the program map to real-world objects like an account in bank, student in college etc.

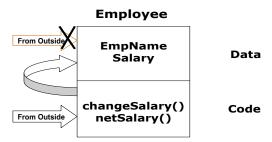

Three basic principles of OOP are:

Encapsulation

- Inheritance
- Polymorphism

Encapsulation

- ☐ Binds or encapsulates data and code that processes data.
- ☐ Protects instance variables (data) by not allowing them to be accessed from outside the object.
- ☐ Provides a set of functions (methods) that are accessed from other objects.
- Increases control as each object is independent with its data, which is private, and a set of functions, which can be called from other objects.
- ☐ A class in Java defines data and code that is to be encapsulated.

In the above example the class **Employee** has two instance variables – EmpName and Salary and two methods – changeSalary() and netSalary().

Instance variables can be accessed only by methods that are part of the class – changeSalary() and netSalary().

Class vs. Object

Class is the description of a collection of similar objects. Class defines the instance variables and methods to be encapsulated.

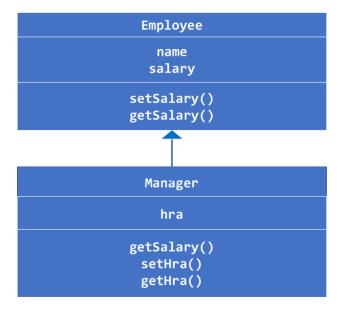

Class denotes a category of objects. It is blueprint for creating objects. Example: Employee, Product, Student etc.

Instance variables are used to store data and **methods** perform operations on the data.

Object is an instance of the class. Memory is allocated only when an object of the class is created. Methods are called using an object. Example: An employee, a student etc.

Inheritance

Ш	Allows a class to be created from another class thereby inheriting all members
	of another class.
	Allows reusability of existing classes.
	New classes may add new members and override existing members of the
	inherited class.
	Class being inherited is called as superclass and the class created from existing
	class is called as subclass.
	Inheritance represents "IS A" relationship between classes. For example,
	Manager is extending Employee because Manager is an Employee. A
	SavingsAccount extends Account because SavingsAccount is an Account.
	Hierarchies can be built using inheritance.
	_

In the above example, **Manager** class inherits all the data members and methods of **Employee** class. It adds **hra** and **setHra**() members and overrides **getSalary**() method.

Overriding is the process where the subclass (Manager) is creating a method with the same signature as a method in the superclass (Employee).

Java allows a class to extend only one class – single inheritance.

Multiple inheritance, where a class can be created from multiple classes, is NOT permitted in Java.

Polymorphism

- ☐ Allows multiple methods performing the same operation to have the same name.
- ☐ Compiler invokes one of the multiple methods depending upon the context (parameters passed to method).
- ☐ Programmer need not remember multiple names.

In the following example, all three functions returning maximum of two values are given same name.

```
max(int ,int)
max(long, long)
max(String,String)
```

Depending upon which data type is passed as the parameter to **max** function, one of the three functions is invoked by the compiler.

Polymorphism may be implemented either at compile-time (method overloading) or at run-time (dynamic method dispatch).

60

Creating a Class

A class is like user-defined data type. A class describes data to be stored and processed. The following is the syntax used to create a class.

```
access class classname
{
    [access] instance-variable-declaration;
    [[access instance-variable-declaration]] . . .

    [access] returntype methodname ([parameterlist])
    {
        // body of the method
    }
    .
    .
}
```

Access may be *private*, *public*, *protected* or *default* (no access) for instance variables and methods.

NOTE: Generally, class names are created using Pascal case naming convention - first letter of each word in uppercase and remaining in lowercase. Method names are created using Camel case naming convention – first word in lowercase and first letter of remaining words in uppercase and remaining letters in lowercase.

The following is the **UML** (Unified Modeling Language) diagram to represent *Employee* class. Minus (-) sign denotes **private** access and plus (+) sign denotes **public** access.

```
Employee

- name : String
- salary : String

+ init(name, salary)
+ print() : void
+ setSalary(salary) : void
+ getSalary() : double
```

NOTE: Name of .java file and public class name must be same. A single .java file can have multiple classes (but only one of them can be public). When you compile .java file, each class in the file will have a corresponding .class file.

Employee.java

This file contains definition for class Employee.

```
01:
    public class Employee {
02:
        private String name;
        private int salary;
03:
        public void init(String n, int sal) {
04:
05:
            name = n;
            salary = sal;
06:
07:
08:
        public void print() {
            System.out.println(name);
09:
            System.out.println(salary);
10:
11:
        public void setSalary(int sal) {
12:
            salary = sal;
13:
14:
15:
        public int getSalary() {
            return salary;
16:
17:
        }
18: }
```

TestEmployee.java

This file contains definition for class TestEmployee. Function main() in TestEmployee does the following:

- ☐ Creates an object reference of **Employee** class.
- ☐ Creates an object of Employee class.
- ☐ Calls methods of Employee class using object reference.

```
public class TestEmployee {
01:
        public static void main(String[] args) {
02:
          Employee e;
                              //object reference
03:
          e = new Employee(); //create an object of Employee
04:
05:
          e.init("Jonathan", 35000);
06:
          e.print();
07:
08:
          e.setSalary(55000);
09:
          if (e.getSalary() > 50000)
10:
              System.out.println("Fat salary");
11:
12:
      }
13: }
```

If you compile **Employee.java**, **TestEmployee.java** and run, it generates the following output:

```
Jonathan
35000
Fat salary
```

Object Reference

Object

Constructor

- A method in the class with the same name as the class name.
- ☐ Invoked automatically whenever an object of the class is created.
- ☐ Used to initialize instance variables of the class.
- ☐ Doesn't contain any return type not even void.

```
01: public class Number {
02:    private int num;
03:    // constructor
04:    public Number() {
05:        num = 1;
06:    }
07: }
```

In the above, **Number** class has a constructor that is used to initialize instance variable *num*. When an object of **Number** class is created, Java automatically calls the constructor.

```
Number n = new Number(); // calls constructor
```

Constructor can take parameters and use those parameters for initializing instance variables.

```
01: public class Number {
02:  private int num;
03:  public Number(int n) {
04:    num = n;
05:  }
06: }
```

The above constructor is called whenever an object is created.

```
Number n = new Number(10);
```

NOTE: If no constructor is explicitly created then Java creates a constructor with no parameters (default constructor). But Java doesn't provide this constructor once a user-defined constructor is created in the class.

The following is **Employee** class with constructor instead of **init()** method :

```
class Employee {
01:
        private String name;
02:
        private int salary;
03:
        public Employee(String n, int sal) {
04:
05:
           name = n;
           salary = sal;
06:
07:
        // remaining code
08:
09: }
```

```
01: class UseEmployee {
02:    public static void main(String[] args) {
03:         Employee e = new Employee("Jonathan", 25000);
04:    }
05: }
```

66

Overloading Methods

- ☐ It is possible to define two or more methods with the same name within the same class provided the parameters of the methods are different.
- Overloading methods is one way of implementing polymorphism.
- ☐ Methods can be overloaded based on type/number of parameters.
- ☐ Methods cannot be overloaded based on return type.

The following example demonstrates overloading methods in a class.

```
01: class Test {
     void m1(int n) { }
02:
     void m1(String s) { }
03:
    void m1(String s, int n) { }
04:
05: void m1(int n, String s) { }
     // Not allowed as methods differ only by return type
06:
           m2(int n) {}
07:
     int
     long m2(int n)
08:
                      {}
09:
```

Overloading Constructors

Just like how it is possible to overload methods of a class, it is also possible to overload constructors of the class.

```
01: public class Number {
02:    int num;
03:    public Number() {
04:        num = 1;
05:    }
06:    public Number(int n) {
07:        num = n;
08:    }
09: }
```

First constructor is called when an object is created without passing any parameter and second constructor is called when an object is created by passing a single **int** as parameter.

```
Number n1 = new Number();  // calls constructor Number()
Number n2 = new Number(100); // calls Number(int)
```

NOTE: It is NOT possible to create an object unless Java can invoke one of the constructors.

```
01: class A {
02:    int n;
03:    public A(int num) {
04:        n = num;
05:    }
06:    public A(String s) {
07:        n = Integer.parseInt(s);
08:    }
09: }
```

Third line doesn't compile as Java cannot call any constructor.

```
A obj1 = new A(10);
A obj2 = new A("99");
A obj2 = new A(); // not possible
```

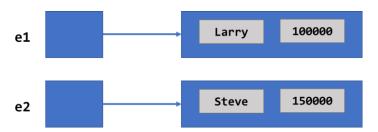

In order to create an object without passing any parameter at the time of creation, the class must have a constructor that takes no parameter or it must have default constructor.

Object Reference

Object reference is a variable that references an object. An object in Java is accessed using object reference.

```
Employee e1; // create object reference of Employee class
// create an object and make e1 referencing it
e1 = new Employee("Larry",100000);

//create object reference and object
Employee e1 = new Employee("Larry",100000);
Employee e2 = new Employee("Steve",150000);
```

Comparing object references

If two object references of the same class are compared, only references are compared but NOT contents of the objects.

NOTE: If you compare two object references, only the references are compared and not the contents of the object that they point to.

NOTE: Only == and != relational operators are allowed with object references.

Assignment between two object references

It is possible to assign one object reference to another. But what we effectively copy is not the contents of an object to another, instead one object reference to another.

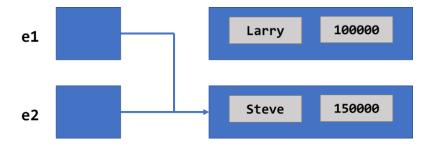

The following example and picture demonstrate what happens when an object reference is copied to another.

```
Employee e1, e2;

e1 = new Employee("Larry",100000);

e2 = new Employee("Steve",150000);

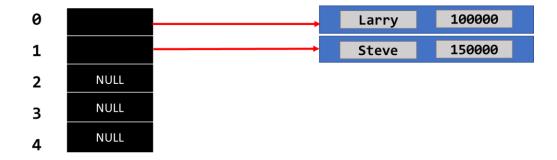

e1 = e2; // e1 and e2 point to same object
```

Array of objects

- ☐ Java supports array of objects of a class.
- ☐ When an array of objects is created only object references that can point to objects of class are created.
- ☐ The default value of each element is null and object reference must be made to point to an object explicitly before it is used.

```
Employee [] e;
// Create an array of 5 Employee object references
e = new Employee[5];
e[0] = new Employee("Larry",100000);
e[1] = new Employee("Steve",150000);
```

The this reference

- ☐ Keyword *this* references invoking object.
- ☐ Used by methods to implicitly access members of the calling object.
- ☐ Used to access instance variables when parameters and instance variables have same names.
- ☐ The **this** reference is made available to each non-static method automatically.
- ☐ Used to call a constructor from another constructor.

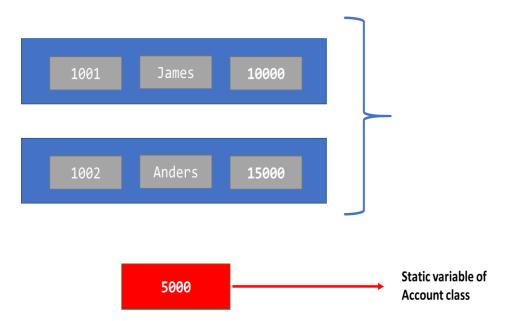

The following constructor uses this reference to access instance variables as parameters and instance variables have same names.

NOTE: When instance variables and parameters are having the same name, parameters of the method take precedence over instance variables. In general, local variables always take precedence over non-local variables.

```
01: class Employee {
02:    private String name;
03:    private int salary;
04:    public Employee(String name, int salary) {
05:        this.name = name;
06:        this.salary = salary;
07:    }
08: }
```

Static Variables

- A static variable, otherwise known as class variable, is a variable that is associated with class and not an object.
- ☐ Defined using keyword **static.**
- ☐ Exist only for once for the entire class.
- ☐ Static variables that are declared as **final** are used as constants.

Static Methods

Static methods are same as normal methods except that they can be invoked
with class name and need not be invoked by any object.

- ☐ Defined using keyword **static**.
- ☐ Do not have **this** reference.
- Static methods cannot invoke non-static methods and cannot access instance variables as they do not have access to any specific object (this reference) refer to code below.
- ☐ Generally used to access and manipulate static variables.

```
public class StaticTest {
01:
        private int iv;
02:
        private static int sv;
03:
04:
        public static void main(String[] args) {
05:
          iv = 10; // not valid
          StaticTest obj = new StaticTest();
06:
          obj.iv = 10; //valid as we use object to access iv
07:
        }
08:
09: }
```

Why main() is a static method?

Function **main()** must be declared as static as it is called using class name by JVM. For example, when you invoke

Java Hello

It will be converted to a call to main as follows:

Hello.main(parameter)

Other examples for static members are Integer.parseInt(), Math.abs() and System.out.

NOTE: Java does not allow any function to be defined outside the class. Methods that can be used without creating an object are declared static, so that they can be called using class name. This also saves the time taken to create and release an object.

	Variable	
Method	Static	Instance
Instance	√ .	√
Static	√	X

Final Variable

- ☐ Java allows variables to be declared as final using **final** keyword.
- ☐ Final variables cannot change value once they are assigned a value.
- Final variables are generally static variables as it generally makes no sense to have the same value for a variable in each object of the class.
- Final variables must be assigned a value before constructor of the object is completed.

```
class Account {
  public static final int MINBAL = 500;
}
```

Variable MINBAL is accessed using class name from outside the class as it is static and public variable. Minbal cannot be changed as it is final and initialized to 500.

```
System.out.println(Account.MINBAL);
```

```
Employee

- name : String
- salary : String
- hraper : double

+ Employee(name, salary)
- print() : void
+ setSalary(salary) : void
+ getSalary() : double
+ setHraper(hraper) : void
```

In the above UML diagram, static members – **hraper** variable and **setHraper**() method are **underlined** to indicate that they are static members of the class.

78

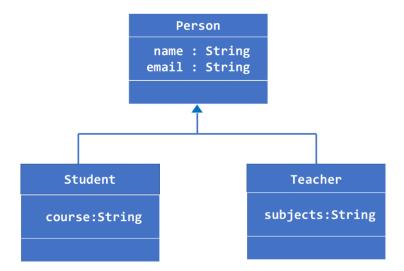

The following code shows how to implement Employee class with static variables – **hraper** and static method **setHraper**().

```
01:
    public class Employee {
92.
        private String name;
03:
        private double salary;
        private static double hraper = 20;
04:
        public Employee(String name, double salary) {
05:
             this.name = name;
06:
07:
             this.salary = salary;
08:
        public void setSalary(double salary) {
09:
             this.salary = salary;
10:
11:
        public double getSalary() {
12:
13:
             return this.salary +
                     this.salary * Employee.hraper / 100;
14.
15:
        }
        public static void setHraper(double hra) {
16:
              Employee.hraper = hra;
17:
        }
18:
19:
```

```
01: public class UseEmployee {
02:    public static void main(String[] args) {
03:         Employee e = new Employee("Jason", 30000);
04:         System.out.println(e.getSalary());
05:         Employee.setHraper(25);
06:         System.out.println(e.getSalary());
07:    }
08: }
```

Inheritance

- ☐ Allows a new class to be created from an existing class.
- ☐ Keyword **extends** is used to create a new class that extends an existing class.
- ☐ Existing class is called as **superclass** and new class is called as **subclass**.
- ☐ Inheritance represents **Is A** relationship. For example, Student is a Person, Car is a Vehicle etc.

The following code demonstrates creating **Person** class and **Teacher** classes.

```
01:
    class Person {
        protected String name, email;
02:
        public Person(String name, String email) {
03:
04:
            this.name = name;
05:
            this.email = email;
06:
07:
        public void print() {
08:
            System.out.println(this.name);
            System.out.println(this.email);
09:
10:
        }
11:
        public void setEmail(String email) {
            this.email = email;
12:
        }
13:
14: }
```

NOTE: Access **protected** allows the members to be accessed from subclasses also.

```
class Teacher extends Person {
01:
      protected String subjects;
02:
03:
      public Teacher(String name, String email,
                      String subjects) {
04:
            super(name,email); // must be first statement
05:
            this.subjects = subjects;
06:
07:
08:
      @Override
      public void print() { // overrides print() of Person
09:
10:
            super.print();
11:
            System.out.println(subjects);
12:
      public void setSubjects(String subjects) {
13:
            this.subjects = subjects;
14:
15:
      }
16: }
```

NOTE: Symbol # in UML diagram specifies protected access.

```
01: class TestPerson {
       public static void main(String args[]) {
02:
          Teacher t = new Teacher("Srikanth",
03:
              "srikanthpragada@yahoo.com", "Java, .Net");
04:
05:
          t.print();
06:
          t.setEmail("srikanthpragada@gmail.com");
          t.setSubjects("Java, .Net, Python, DS");
07:
08:
       }
09: }
```

Constructors in Inheritance

When an object of subclass is created then Java automatically calls default constructor of the super class from the constructor of subclass.

But, when there is no default constructor in superclass, we must explicitly call the constructor of superclass using **super** keyword and required parameters (as we did in **Teacher** class).

Overriding Methods

When a method in the subclass has the same name and signature of a method in superclass, the method in subclass is said to be overriding the method in superclass.

Method print() of Person class is overridden in subclass Teacher.

Rules re	lated to	overriding:
----------	----------	-------------

The arguments list must match exactly. Otherwise, it becomes overloading.
Return type must be same as, or a subclass of, the return type of original
method.
Access level CANNOT be more restrictive than the original. For example, if
superclass method is public, then subclass method cannot be protected.
A final method cannot be overridden.
Static method cannot be overridden.
Only inherited methods can be overridden. Private methods of superclass
cannot be overridden as they are not inherited.

@Override Annotation

Annotation **Override** indicates that a method declaration in subclass is intended to override a method declaration in a superclass.

If a method annotated with this annotation does not override a superclass method, compiler generates an error message.

Overloading vs. Overriding

When you create a method in subclass with the same name as a method in super class but with different set of parameters, it is called as overloading and not overriding.

The following example shows the difference between overriding and overloading.

```
01: class C1{
02:
        public void m1(String msg) {
03:
04:
        public void m2(int n) {
05:
06: }
07:
08: class C2 extends C1 {
        // overloads m1() in class C1
09:
        public void m1() {
10:
11:
        }
12:
13:
        // overrides m2() in class C1
14:
        public void m2(int n) {
15:
16:
```

Using super keyword to access superclass version

The **super** keyword in subclass is used to access superclass. The super keyword can be used to:

- Access a method of superclass that is overridden by a member in the subclass.
- ☐ Invoke the constructor of super class from the constructor of subclass.
- ☐ The super keyword can refer only to the immediate super class in the hierarchy.

NOTE: While calling the constructor of the superclass from subclass's constructor, the call must be the first statement in the constructor of the subclass.

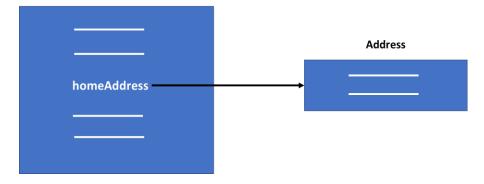

"Has A" Relationship

When a class contains a variable that refers to another class, the class is said to have "Has A" relationship with the other class.

In the following example, **Customer** class has "has a" relationship with **Address** class as it has a variable of class **Address**.

```
class Address {
    // instance variables & methods
}
class Customer {
    private Address homeaddress;
    // other variables and methods
}
```

Customer

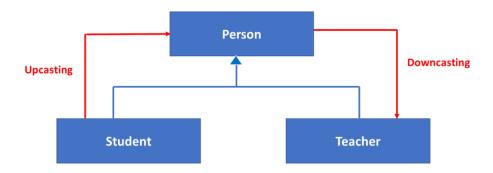

86

Downcasting and Upcasting

Java allows an object reference of superclass to refer to an object of subclass. This is the heart of runtime-polymorphism in Java.

Superclass is more general form of subclass. Subclass is more specific form of superclass. Person is more general form of Student. In other words, a Student is always a Person. So, wherever Java expects Person, a Student can be used.

NOTE: Remember superclass and subclass share IS A relationship. A Student is always a Person.

Upcasting is casting an object to a class higher in the inheritance tree. When an object of **Teacher** is assigned to **Person**, it is called as upcasting. Upcasting is implicit in Java.

Downcasting is casting an object to a class down in the *hierarchy tree*. When an object of Person is cast to Teacher, it is called as **Downcasting**.

Downcasting must be done explicitly using typecasting syntax as follows:

```
Person p = new
Teacher("Hunter","hunter@servlets.com","Java");
Teacher f = p; // doesn't compile
Teacher f = (Teacher) p; // Downcasting explicitly
```

NOTE: Downcasting is explicit and Upcasting is implicit. Downcasting is possible between a superclass and subclass only. For example, it is not possible to convert a String object to Person object as String and Person classes are not related.

The instanceof operator

Operator **instanceof** is used to check whether an object reference refers to an object of specified class or one of its subclasses.

object-reference instanceof class

```
Person p = new Teacher("abc","abc@gmail.com","java");
System.out.println(p instanceof Teacher);
System.out.println(p instanceof Person);
System.out.println(p instanceof Student);
```

Pattern matching for instanceof

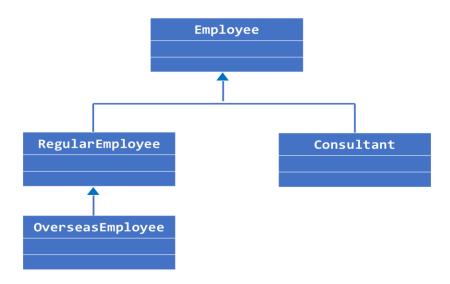

- ☐ Pattern matching is a feature finally standardized in Java 16, though it was introduced as preview feature earlier.
- ☐ It converts superclass object reference to subclass if it points to specified subclass.
- ☐ Variable created by **instanceof** can be used only in the current block.

The following program checks whether object reference p points to Student object and if so, converts it to Student object:

```
Person p = new Teacher("Mike","mike@gmail.com","Java");
if (p instanceof Teacher t) {
        t.setSubjects("Java, Java EE");
}
```

Multi-level inheritance

Java supports multi-level inheritance. In this, a class is extended by another class, which is again extended by another class. The following picture shows multi-level inheritance.

In the above example, **Employee** class is inherited into **RegularEmployee** class, which in turn is inherited into **OverseasEmployee**.

Constructors of classes in inheritance must be called in the order of inheritance.

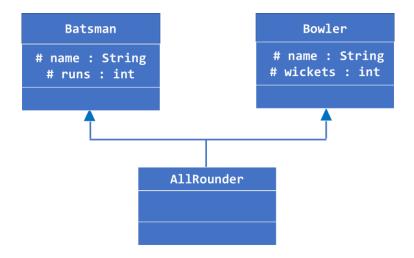

When you create an object of **OverseasEmployee**, constructor of **Employee** class is called first then constructor of **RegularEmployee** and then finally constructor of **OverseasEmployee**.

Java tries to call constructor of superclass from subclass's constructor using **super()** statement. However, if that is not adequate, you must explicitly call constructor of superclass using super keyword by passing required parameters.

Multiple Inheritance

Java **does NOT** support multiple inheritance, where a single class extends two or more classes. It means, Java doesn't allow two or more classes to be inherited into a single class.

In the following diagram, **AllRounder** is extending **Batsman** and **Bowler**, which is not supported by Java.

The reason for Java to avoid multiple inheritance is the ambiguity caused by multiple inheritance. For example, **AllRounder** has two instances of **name** variable as one comes from **Batsman** and another comes from **Bowler**. This leads to *ambiguity*.

Runtime Polymorphism

☐ It is the process by which a call to an overridden method is resolved at	
	instead of compile-time.

- ☐ It is based on the concept that an object reference of the super class can refer to an object of any subclass in the hierarchy.
- ☐ Runtime polymorphism occurs when an overridden method is called using an object reference of superclass.
- ☐ Java decides which method to call (superclass or subclass) based on the object pointed by object reference of superclass.
- ☐ Also called as *late binding* or *dynamic method dispatch*.

The following code shows how Java calls appropriate method depending on the object pointed by object reference.

```
Person p;
p = new Person(...);
p.print();

// object ref. of superclass points to object of subclass
p = new Teacher(...);
/* call to print() method calls print() of subclass as p
points to object of subclass. */
p.print(); // calls print() of subclass
```

NOTE: Dynamic method dispatch is applied only to method that is defined in superclass, overridden in subclass and invoked using an object reference of superclass.

Abstract Method ☐ Keyword abstract is used to create abstract methods. ☐ Abstract method doesn't contain body. ☐ Must be overridden in subclass. Otherwise, subclass must be declared abstract. ☐ If there is any abstract method in the class then class must be declared as abstract.

☐ Mutually exclusive with final method – a method cannot be declared as final and abstract.

Abstract Class

stract class using keyword abstract.
Defined using abstract keyword.
Cannot instantiate (create) objects of abstract class.
However, an object reference of abstract class can be declared.
Generally, contains one or more abstract methods.
A class can be declared as abstract even though it doesn't contain any abstract methods.
Can contain other non-abstract members such as methods and instance variables.

Final Variable, Method, Class and Parameter

- ☐ Keyword **final** is used to declare final variables, methods and classes.
- A final variable is a variable whose value cannot be changed once the variable is assigned a value.
- ☐ Final method is a method that cannot be overridden in the subclass.
- ☐ Final class cannot be extended (inherited). There is no subclass for final class.
- ☐ You can declare parameters as **final** to ensure that the value of the parameter doesn't change during the execution of the method.

```
public void fun(int x, final int y) { }
```

The following example demonstrates how to use abstract method, abstract class, final method and runtime polymorphism.

```
01: abstract class Employee {
02:
        protected String name, desg;
        public Employee(String name, String desg) {
03:
04:
            this.name = name;
            this.desg = desg;
05:
06:
        final public String getDesg() {
07:
08:
            return desg;
09:
        final public void setDesg(String desg) {
10:
            this.desg = desg;
11:
12:
13:
        final public String getName() {
14:
            return name;
15:
        public abstract int getPay();
16:
17: }
```

```
18: class RegularEmployee extends Employee {
19:
      protected int salary;
      public RegularEmployee(String name, String desg,
20:
21:
                              int salary) {
22:
          super(name, desg);
          this.salary = salary;
23:
24:
25:
      @Override
26:
      public int getPay() {
          return salary;
27:
28:
      }
29: }
30:
31: class Consultant extends Employee {
      protected int nohours, hourrate;
32:
33:
      public Consultant(String name, String desg,
34:
                              int nohours, int hourrate) {
        super(name, desg);
35:
        this.nohours = nohours;
36:
37:
        this.hourrate = hourrate;
38:
39:
      @Override
40:
      public int getPay() {
        return nohours * hourrate;
41:
42:
      }
43: }
```

```
44:
    public class TestEmployee {
      public static void main(String[] args) {
45:
       Employee employees [] =
46:
       {new RegularEmployee("Steve", "Programmer", 25000),
47:
        new Consultant("Kevin", "DBA",10,500),
48:
49:
        new RegularEmployee("Tom", "System Analyst", 45000)
50:
       };
51:
       for(Employee e: employees)
           System.out.printf("%s:%d\n",
52:
                           e.getName(), e.getPay());
53:
54:
      }
55: }
```

```
Steve:25000
Kevin:5000
Tom:45000
```

98

Sealed Classes

Sealed classes let you restrict class hierarchies to only certain classes.
Sealed classes are declared with modifier sealed and specify which classes are
permitted to extend the class using permits modifier.
Only the classes defined after the keyword permits are allowed to extend the
sealed class.
Classes mentioned after permits must be in same package or module.
Every permitted subclass must explicitly extend the sealed class.
Every permitted subclass must use one of the modifiers - final, sealed, or non-
sealed.
Concreate subtypes are implicitly final .

```
01: sealed class Course permits OnlineCourse, OfflineCourse{
02:
03: }
04:
05: final class OnlineCourse extends Course {
06:
07: }
08:
09: non-sealed class OfflineCourse extends Course {
10:
11: }
12:
13: class WeekendCourse extends OfflineCourse {
14:
15: }
```

Initialization Blocks

- ☐ Object initialization block is executed when object is created.
- ☐ Static initialization block is executed when class is loaded.
- ☐ Initialization block is run after super-constructor has run.
- Blocks are run in the order in which they appear in the class.
- ☐ Initialization block cannot have parameter and cannot return any value.
- Object initialization blocks are executed irrespective of which constructor is executed. So, they can be used to contain code that all constructors need to share.

```
01:
    class A {
        // Object initialization block
02:
03:
            System.out.println("Init Block In A");
04:
05:
        public A() {
06:
            System.out.println("Constructor of A");
07:
        }
08:
09:
10:
        // Static initialization block
        static {
11:
12:
            System.out.println("Static Init Block Of A");
13:
        }
14: }
15:
16: class B extends A
17: {
18:
        public B() {
19:
            System.out.println("Constructor of B");
20:
        public B(String message){
21:
            System.out.println("Constructor with message:
22:
23:
                                                    + message);
24:
```

```
// Object initialization block
25:
26:
        {
            System.out.println("First Init Block In B");
27:
        }
28:
29:
        {
30:
           System.out.println("Second Init Block In B");
31:
32:
        }
33:
        static {
34:
           System.out.println("Static Init Block Of B");
35:
      }
36:
37: }
38:
39: public class InitBlockDemo {
40:
        public static void main(String[] args) {
41:
           B obj = new B();
           System.out.println("=======");
42:
           B obj2 = new B("Second Object");
43:
        }
44:
45: }
```

When you run the above program, you will get the following output:

Java Library Part - 1

Object class

Object class is one of the standard classes in Java API.
All other classes in Java are subclasses of Object class.
A class declaration without extends clause, implicitly extends Object class.
So, a reference to Object class can refer to an object of any class in Java.

Method	Meaning
Object clone()	Creates a new object that is same as the object being
	cloned. Default implementation does shallow copying –
	only primitive value and references are copied.
	Override this method to provide deep copying.
boolean	Compares the contents of two objects and returns true
equals(Object)	if contents are same. Default implementation compares
	only references and not contents. Override this method
	to provide value-based comparison.
void finalize()	Called before an unused object is released by garbage
	collector. Default implementation does nothing.
int hashCode()	Returns the hash code associated with the invoking
	object. Hash code is used when object is used with
	hashing - HashSet. When two objects are equal then
	hash codes for those two objects must also be equal.
String toString()	Returns a string that describes the object. Default
	implementation returns
	classname@hashcode-in-hex.
final class getClass()	Returns an object of type Class related to object.

NOTE: If two objects are equal according to the **equals** (Object) method, then calling the **hashCode**() method on each of the two objects must produce the same integer result.

The following **final** methods of Object class are related to multithreading.

final void notify()	Resumes execution of the thread that is waiting to be notified.
final void notifyAll()	Resumes execution of all threads that are waiting to be notified.
final void wait()	Causes the current thread to wait until the object notifies the thread.

The following program shows default implementation of methods in **Object** class.

```
01: class Time {
        private int hours, mins, secs;
02:
        public Time(int hours, int mins, int secs) {
03:
            this.hours = hours;
04:
05:
            this.mins = mins:
06:
            this.secs = secs;
07:
        }
08:
09: public class TestTime {
        public static void main(String[] args) {
10:
            Time t1 = new Time(10, 20, 30);
11.
12:
            Time t2 = new Time(10, 20, 30);
13:
14:
            System.out.println(t1.toString());
            System.out.println(t2.equals(t1));
15:
16:
       }
17:
```

The above program generates the following output:

```
Time@19821f
false
```

In the following example, we override **equals()**, **hashCode()**, and **toString()** methods.

```
01: // class to override methods in Object class
02: class Time {
03:
      private int hours, mins, secs;
      public Time(int hours, int mins, int secs) {
04:
05:
        this.hours = hours:
06:
        this.mins = mins:
07:
        this.secs = secs;
08:
09:
      public int getTotalSeconds() {
10:
        return hours * 60 * 60 + mins * 60 + secs;
11:
12:
      @Override
13:
      public int hashCode() {
14:
        return hours;
15:
16:
      @Override
17:
      public boolean equals(Object obj) {
        if (obj instanceof Time) {
18:
19:
         Time t = (Time) obj;
         return t.getTotalSeconds()==this.getTotalSeconds();
20:
21:
        }
22:
        else
23:
         return false;
24:
25:
      @Override
26:
      public String toString() {
27:
     return String.format
                       ("%02d:%02d:%02d", hours, mins, secs);
28:
29:
      }
30: }
```

```
public class TestTime {
31:
        public static void main(String[] args) {
32:
           Time t1 = new Time(10, 20, 30);
33:
34:
           Time t2 = new Time(10, 20, 30);
           Time t3 = new Time(15, 15, 15);
35:
36:
           System.out.println(t1.toString());
37:
           System.out.println(t1.equals(t2));
38:
           System.out.println(t1.equals(t3));
39:
        }
40:
41: }
```

Output generated by the above program is as follows:

```
10:20:30 true false
```

Records

- A record is a class for which the following artifacts are automatically defined by Java:
 - ✓ The constructor that takes all fields mentioned
 - ✓ Getter methods with field names
 - √ toString()
 - √ hashCode() and equals()
- ☐ Fields of records are automatically made final.
- ☐ **Record** is the common base class of all Java language record classes.
- ☐ A record class declaration does not have an **extends** clause.
- ☐ A record class is implicitly **final**, and cannot be **abstract**.
- ☐ The fields derived from the record components are **final**.
- ☐ A record class can declare static methods, fields, and initializers.
- ☐ A record class can declare instance methods.
- ☐ A record class can implement interfaces.

```
var c1 = new Contact("A", "a@gmail.com", "123456");
var c2 = new Contact("A", "a@gmail.com", "123456");
System.out.println(c1.toString());
System.out.println(c1.equals(c2));
System.out.println(c1.email()); // getter method
```

```
Contact[name=A, email=a@gmail.com, mobile=123456]
true
a@gmail.com
```

String Class

- ☐ String is one of the standard classes of Java.
- ☐ An object of String class represents a collection of characters (string).
- ☐ Provides methods required to manipulate a string.

NOTE: String represented by String class is **immutable**. That means once we create a string, its value cannot be modified.

```
String()
String(char[])
String(String)
```

The following are important methods of **String** class.

Method	Meaning
char charAt(int)	Returns the character at the given position.
boolean endsWith(String)	Returns true if string ends with the given
	string.
String concat(String)	Appends string to invoking string and returns
	concatenated string.
boolean Contains(String)	Returns true if string contains the given string.
int indexOf(String)	Returns the position of the substring in the
	main string or -1 on failure.
int indexOf (String, frompos)	Same as above, but starts search at the given
	position.
int lastIndexOf (String)	Returns position of the substring from the end
	of main string.
int lastIndexOf(String, frompos)	Same as above, but starts search at the given
	position.
int length()	Returns the length of the string.
String join(String delimiter,	Returns a string by joining given string with
String elements)	delimiter.

boolean startsWith (String)	Returns true if string starts with the given string.
String substring (int from, int to)	Returns a substring that starts at <i>from</i> and ends at <i>to</i> in main string.
String to Lawren Coop ()	
String toLowerCase()	Returns the string after converting it to
	lowercase.
String toUpperCase()	Returns the string after converting it to
	uppercase.
String trim()	Trims spaces on both sides of string.
String replace	Replaces <i>old</i> character in the string with <i>new</i>
(char old,char new)	character.
static String valueOf (T v)	Converts the given value to string.
String [] split(String delims)	Splits a string into multiple strings based on
	the given delimiter.
String indent(int n)	Adjusts the indentation of each line of this
	string based on the value of n.
boolean isBlank()	Returns true if the string is empty or contains
	only white space codepoints, otherwise false.
Stream <string> lines ()</string>	Returns a stream of lines extracted from this
, ,	string, separated by new line char.
String repeat (int count)	Returns a string whose value is the
	concatenation of this string repeated count
	times.
String strip()	Returns a string whose value is this string,
5 1 17	with all leading and trailing whitespaces
	removed.
String stripLeading()	Returns a string whose value is this string,
0 1 1 30	with all leading whitespaces removed.
String stripTrailing()	Returns a string whose value is this string,
	with all trailing whitespaces removed.

```
public class StringDemo {
01:
      public static void main(String args[]) {
02:
       String s1 = new String("Java Language");
03:
       String s2 = "Java EE";
04:
05:
       // comparing two strings based on values
96:
07:
       if(s1.equals(s2))
          System.out.println("Equal");
08:
09:
                                                  // 7
10:
       System.out.println(s2.length());
11:
       System.out.println(s1.charAt(0));
                                                   // J
       System.out.println(s1.startsWith("Java"));// true
12:
13:
       System.out.println(s1.endsWith("Java")); // false
       System.out.println(s1.indexOf("a"));
                                                  // 1
14:
       System.out.println(s1.indexOf("a", 4));
15:
                                                  // 6
       System.out.println(s1.lastIndexOf("a"));
16:
                                                  // 10
       System.out.println(s1.substring(0,4));
17:
                                                  // Java
       System.out.println(s1.toUpperCase());// JAVA LANGUAGE
18:
19:
       // original string remains the same
       System.out.println(s1);
20:
                                             // Java Language
21:
22:
       // split the string based on space
       String words[] = s1.split(" ");
23:
       System.out.println("\nWords\n");
24:
25:
       for (String w : words)
               System.out.println(w);
26:
27:
```

```
28:
       String langs = String.join(",","Java","Python","C#");
29:
       System.out.println(langs); // Java, Python,C#
30:
       System.out.println(" Java SE ".strip()); //Java SE
31:
       System.out.println("Java SE\nJava EE".indent(5));
32:
               Java SE
33:
       //
       //
34:
               Java EE
35:
     System.out.println("*".repeat(5)); // *****
System.out.println(" ".isBlank()); // true
36:
37: }
38: }
```

112

StringBuffer Class

StringBuffer represents a mutable character string thus allowing string to be modified.

```
StringBuffer(String)
StringBuffer(int capacity)
StringBuffer()
```

Method	Meaning
void setCharAt(index,char)	Changes character at the given position.
StringBuffer append(String)	Appends string at the end.
StringBuffer append(char)	Appends character at the end.
StringBuffer append(char[])	Appends character array at the end of buffer.
StringBuffer insert(offset,data)	Inserts the given data at the given offset in
	the buffer.
StringBuffer deleteCharAt(index)	Removes character at the index.
StringBuffer delete	Removes characters from start to end.
(int start, int end)	
StringBuffer reverse()	Reverses string buffer.

```
01:
    public class SBDemo {
02:
      public static void main(String args[]) {
       StringBuffer sb = new StringBuffer("Java ");
03:
       sb.append("EE");
04:
       System.out.println(sb);
05:
                                   // Java EE
       sb.insert(0,"Oracle ");
06:
       System.out.println(sb);
07:
                                   // Oracle Java EE
       sb.delete(0,6);
08:
       System.out.println(sb);
09:
                                    // Java EE
10:
      }
11: }
```

NOTE: StringBuilder class was introduced in Java 5.0. It is same as StringBuffer except that it is NOT synchronized. So StringBuilder is not thread-safe but could be faster than StringBuffer.

StringJoiner Class

StringJoiner is used to construct a sequence of strings separated by a delimiter and optionally prefix and suffix.

```
StringJoiner(String delimiter)
StringJoiner(String delimiter, String prefix, String suffix)
```

Method	Meaning
StringJoiner add	Adds a copy of the given CharSequence value as
(CharSequence value)	the next element of the StringJoiner value.
StringJoiner merge	Adds the contents of the given StringJoiner
(StringJoiner other)	without prefix and suffix as the next element.
StringJoiner setEmptyValue	Sets the value to be used when no elements have
(CharSequence value)	been added yet, that is, when it is empty.

```
StringJoiner sj = new StringJoiner(",","[","]");
sj.add("Java");
sj.add("C#");
sj.add("Python");
System.out.println(sj.toString()); // [Java,C#,Python]
```

Compact String

- ☐ Compact string is a string that uses only one byte for character instead of 2 bytes as it is the case in Java 8 and before.
- ☐ Java decides whether to use byte[] or char[] to store strings based on character set used.
- ☐ For LATIN-1 representation, a byte array is used and in other cases char array is used (UTF-16 representation).
- ☐ To know whether a string is using char[] or byte[], a field called coder is used internally.
- ☐ The whole implementation is automatic and transparent to developer.
- ☐ Compact strings reduce the amount of memory occupied by strings by half.

String in Java 8

String in Java 9

Math Class

Math class contains a set of **static** methods to support common mathematical functions. It is a final class and cannot be extended.

Static Method	Meaning
T abs(T number)	Returns absolute value.
T min(T n1, T n2)	Returns least of two numbers.
T max(T n1, T n2)	Returns greater of two numbers.
long round(double)	Returns number after rounding it.
double pow(double base,	Returns base raised to power.
double power)	
double random()	Returns a random number that is >=0 and < 1.0.

NOTE: In the above methods T indicates the data type used.

```
01: public class MathDemo {
02: public static void main(String[] args) {
03:    System.out.println(Math.abs(-10));
04:    System.out.println(Math.min(10, 20));
05:    System.out.println(Math.round(10.636));
06:    System.out.println(Math.round(Math.random()*100));
07:    }
08: }
```

Arrays Class

Arrays class provides static methods to search, sort, fill and compare arrays. It provides methods that work on array of any type.

Method	Meaning
int binarySearch	Searches for value using binary search algorithm.
(T array[], T v)	
boolean equals	Compares whether contents of two arrays are equal.
(T array[], T array[])	
<pre>void fill(T array[], T value)</pre>	Fills all elements of an array with the given value.
void sort(T array[])	Sorts the given array.
String toString(T array[])	Returns a string that contains all elements of the
	array.
T [] copyOf	Makes a copy of an existing array to new array with
(T array[], int newlength)	the specified size and returns new array.

```
01: // import Arrays class from java.util package
02: import java.util.Arrays;
03: class ArraysDemo {
      public static void main(String...args) {
04:
05:
       long a[] = new long[5];
       for (int i = 0; i < 5; i ++)
06:
            a[i] = Math.round (Math.random() * 100);
07:
       Arrays.sort(a);
08:
       for (long n : a)
09:
            System.out.println(n);
10:
11:
12:
       int pos = Arrays.binarySearch(a,30);
       if (pos >= 0)
13:
            System.out.printf("Found at : %d", pos);
14:
15:
       else
            System.out.println("Not found");
16:
17:
      }
18: }
```

Calendar Class

Calendar class provides methods and fields to obtain information about date and time. Calendar is an abstract class and an example for its subclass is *GregorianCalendar*.

Static method *getInstance*() is used to return an object of Calendar class that contains system date and time.

Method	Meaning
int get(what)	Returns the value specified by what .
void add (int what, int	Adds <i>value</i> which is specified by <i>what</i> parameter.
value)	
void set (year, month, days,	Sets date and time to given values.
hours, minutes, seconds)	
void setTime(Date)	Sets time to given Date object.

```
01: import java.util.*;
    public class CalendarDemo {
02:
     public static void main(String [] args)
03:
                                   throws Exception {
04:
05:
       //Get system date and time
       Calendar cal = Calendar.getInstance();
06:
07:
       cal.add(Calendar.MONTH, 10);
       System.out.printf ("Year :%d Month:%d
08:
                                                Day:%d",
            cal.get(Calendar.YEAR), cal.get(Calendar.MONTH),
09:
            cal.get(Calendar.DAY OF MONTH));
10:
11:
      }
12: }
```

118

Date Class

An instance of Date class represents a single date and time. Internally date and time is stored as long integer. It is the number of milliseconds from Jan 1, 1970.

Creating an object of **Date** class fills it with system date and time. You can get date and time using **getTime**() method, set date and time using **setTime**() method.

An object of **Date** class is used mainly with **DateFormat** class as its **format**() methods expect an object of Date class.

DateFormat Class

DateFormat is an abstract class used to format dates. You get an instance of DateFormat class to format either date or time by using one of the following methods:

```
DateFormat getDateInstance()
DateFormat getDateInstance(int style)
DateFormat getTimeInstance()
DateFormat getTimeInstance(int style)
```

Argument **style** could be – DEFAULT, SHORT, MEDIUM, LONG or FULL.

Method **format()** is used to format the date or time. It takes an object of **Date** class as parameter.

NumberFormat Class

- ☐ It is an abstract base class for all number formats.
- ☐ Provides the interface for formatting and parsing numbers.
- Supports locale.

```
static NumberFormatgetCurrencyInstance()static NumberFormatgetCurrencyInstance(Locale inLocale)static NumberFormatgetInstance()static NumberFormatgetInstance(Locale inLocale)
```

Compact Number Format

- ☐ Method **getCompactNumberInstance**() returns an object that can be used to format numbers to get compact value of the given number.
- ☐ It returns 1K for 1000, and 1M for 1000000 etc.

SimpleDateFormat Class

It is used to format date and time using custom format. It is a concrete subclass of **DateFormat** class. The following characters can be used to format date and time. For complete list of format characters, see Java Documentation.

Format	What it presents	Example
у	Year	1996; 96
М	Month in year	July; Jul; 07
W	Week in month	2
d	Day in month	10
Н	Hour in day (0-23)	0
h	Hour in am/pm (1-12)	12
m	Minute in hour	30
S	Second in minute	55

```
01: import java.text.*;
02: import java.util.Date;
    public class DateFormatExample {
03:
      public static void main(String[] args) {
04:
05:
            Date d = new Date();
06:
            DateFormat df =
               DateFormat.getTimeInstance(DateFormat.FULL);
07:
08:
            System.out.println(df.format(d));
09:
            DateFormat tf =
               DateFormat.getDateInstance(DateFormat.FULL);
10:
            System.out.println(tf.format(d));
11:
12:
            SimpleDateFormat sdf =
               new SimpleDateFormat("d-MMM-yy HH:mm:ss");
13:
            System.out.println(sdf.format(d));
14:
15:
      }
16:
```

1:53:45 pm India Standard Time Saturday, 1 May, 2021 1-May-21 13:53:45

New Date and Time API

Ч	The Date-Time API uses the calendar system defined in ISO-8601 as the defat
	calendar.
	The core classes are LocalDate, LocalTime, LocalDateTime, ZonedDateTime,
	and OffsetDateTime.
	Most of the classes in the Date-Time API create objects that are immutable.
	This makes objects thread safe.
	Packages java.time, java.time.format, java.time.zone contain new classes.

DayOfWeek Enum

The DayOfWeek enum consists of seven constants that describe the days of the week: MONDAY through SUNDAY. The integer values of the DayOfWeek constants range from 1 (Monday) through 7 (Sunday).

Month Enum

The Month enum includes constants for the twelve months, JANUARY through DECEMBER. The integer value of each constant corresponds to the ISO range from 1 (January) through 12 (December).

LocalDate Class

A LocalDate represents a year-month-day in the ISO calendar and is useful for representing a date without a time. You might use a LocalDate to track a significant event, such as a birth date or wedding date.

Method	Meaning
LocalDateTime atTime	Combines this date with a time to create
(int hour, int minute, int second)	a LocalDateTime.
String format	Formats this date using the specified
(DateTimeFormatter formatter)	formatter.
int get(TemporalField field)	Gets the value of the specified field from
	this date as an int.
int getDayOfMonth()	Gets the day-of-month field.
DayOfWeek getDayOfWeek()	Gets the day-of-week field, which is an
	enum DayOfWeek.
int getDayOfYear()	Gets the day-of-year field.
int getMonthValue()	Gets the month-of-year field from 1 to 12.
int getYear()	Gets the year field.
boolean isLeapYear()	Checks if the year is a leap year.
LocalDate minusDays(long	Returns a copy of this LocalDate with the
daysToSubtract)	specified number of days subtracted.
LocalDate minusMonths(long	Returns a copy of this LocalDate with the
monthsToSubtract)	specified number of months subtracted.
LocalDate minusYears(long	Returns a copy of this LocalDate with the
yearsToSubtract)	specified number of years subtracted.
LocalDate plusDays(long daysToAdd)	Returns a copy of this LocalDate with the
	specified number of days added.
LocalDate plusMonths(long	Returns a copy of this LocalDate with the
monthsToAdd)	specified number of months added.
LocalDate plusYears(long	Returns a copy of this LocalDate with the
yearsToAdd)	specified number of years added.
Stream <localdate> datesUntil</localdate>	Returns a sequential ordered stream of
(LocalDate endExclusive)	dates.

Static Method	Meaning
LocalDate now()	Obtains the current date from the
	system clock in the default time-zone.
LocalDate of(int year, int month, int	Obtains an instance of LocalDate from
dayOfMonth)	a year, month and day.
LocalDate parse(CharSequence text)	Obtains an instance of LocalDate from
	a text string such as 2007-12-03.
LocalDate parse(CharSequence text,	Obtains an instance of LocalDate from
DateTimeFormatter formatter)	a text string using a specific formatter.

124

LocalTime Class

LocalTime represents a time without a timezone.

```
LocalTime now = LocalTime.now();
LocalTime singtime =
LocalTime.now(ZoneId.of("Asia/Singapore"));
```

Method	Meaning
int getHour()	Gets the hour-of-day field.
int getMinute()	Gets the minute-of-hour field.
int getSecond()	Gets the second-of-minute field.
boolean isAfter	Checks if this time is after the specified time.
(LocalTime other)	
boolean isBefore	Checks if this time is before the specified time.
(LocalTime other)	
LocalTime minusHours	Returns a copy of this LocalTime with the
(long hours)	specified number of hours subtracted.
LocalTime minusMinutes	Returns a copy of this LocalTime with the
(long minutes)	specified number of minutes subtracted.
LocalTime minusSeconds	Returns a copy of this LocalTime with the
(long seconds)	specified number of seconds subtracted.
LocalTime plusHours	Returns a copy of this LocalTime with the
(long hours)	specified number of hours added.
LocalTime plusMinutes	Returns a copy of this LocalTime with the
(long minutes)	specified number of minutes added.
LocalTime plusSeconds (long	Returns a copy of this LocalTime with the
seconds)	specified number of seconds added.
int toSecondOfDay()	Extracts the time as seconds of day, from 0 to 24
	* 60 * 60 - 1.

Static Method	Meaning
LocalTime now()	Obtains the current time from the system clock
	in the default time-zone.
LocalTime now	Obtains the current time from the system clock
(Zoneld zone)	in the specified time-zone.
LocalTime of	Obtains an instance of LocalTime from an hour,
(int hour, int min, int sec)	minute and second.
LocalTime parse	Obtains an instance of LocalTime from a text
(CharSequence text)	string such as 10:15.
LocalTime parse	Obtains an instance of LocalTime from a text
(CharSequence text,	string using a specific formatter.
DateTimeFormatter formatter)	

LocalDateTime Class

This class handles both date and time, without a time zone. This class is used to represent date (month-day-year) together with time (hour-minute-second-nanosecond) and is, in effect, a combination of LocalDate with LocalTime.

YearMonth, MonthDay and Year Classes

- ☐ YearMonth represents the month of a specific year.
- ☐ MonthDay represents the day of a particular month, such as New Year's Day on January 1.
- ☐ Year represents a year.

ChronoUnit Enum

- ☐ The ChronoUnit enum provides a set of standard units based on date and time, from milliseconds to millennia.
- ☐ Available constants are DAYS, HOURS, MICROS, MILLENNIA, MILLIS, MINUTES, MONTHS, SECONDS, WEEKS, YEAR.

```
01: import java.time.LocalDate;
02: import java.time.Period;
03: import java.time.temporal.ChronoUnit;
04: import java.util.Scanner;
05: public class AgeCalculator {
     public static void main(String[] args) {
06:
07:
      System.out.print("Enter DOB [yyyy-mm-dd]:");
     Scanner s = new Scanner(System.in);
08:
09:
     String dobstr = s.nextLine();
     LocalDate dob = LocalDate.parse(dobstr);
10:
11:
     LocalDate now = LocalDate.now();
     long years = ChronoUnit.YEARS.between(dob,now);
12:
13:
      System.out.println(years);
      Period p = Period.between(dob,now);
14:
     System.out.printf
15:
          ("%d years, %d months and %d days old!\n",
16:
           p.getYears(), p.getMonths(), p.getDays());
17:
     }
18:
19: }
```

```
Enter DOB [yyyy-mm-dd]:1998-10-24
22
22 years, 6 months and 7 days old!
```

DateTimeFormatter Class

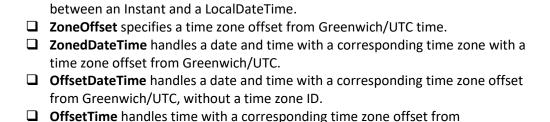

- ☐ Provides format for printing and parsing date-time objects.
- ☐ The following methods are used to obtain an object of DateTimeFormatter:
 - ofLocalizedDate(format)
 - ofLocalizedTime(format)
 - ofLocalizedDateTime(format,format)
 - ofPattern(customFormat)

```
01: import java.time.LocalDate;
02: import java.time.format.DateTimeFormatter;
03: import java.time.format.FormatStyle;
04:
05: public class DateTimeFormatterExample {
06:
      public static void main(String[] args) {
07:
       DateTimeFormatter df =
08:
        DateTimeFormatter.ofLocalizedDate(FormatStyle.FULL);
       LocalDate today = LocalDate.now();
09:
       System.out.println(today.format(df));
10:
11:
       DateTimeFormatter inputFormat =
12:
         DateTimeFormatter.ofPattern("dd-MM-uuuu");
13:
14:
       LocalDate transDate =
15:
         LocalDate.parse("24-10-1998", inputFormat);
       System.out.println(transDate);
16:
17:
       DateTimeFormatter format =
18:
          DateTimeFormatter.ofPattern("dd-MMM-uuuu H:m:s");
19:
       System.out.println
20:
21:
          (LocalDateTime.now().format(format));
22:
      }

Symbol	Meaning	Presentation	Example
u	year	Year	2004; 04
У	year-of-era	Year	2004; 04
D	day-of-year	number	189
M/L	month-of-year	number/text	7; 07; Jul; July; J
d	day-of-month	number	10
Q/q	quarter-of-year	number/text	3; 03; Q3; 3rd
			quarter
W	week-of-month	number	4
E	day-of-week	Text	Tue; Tuesday; T
a	am-pm-of-day	Text	PM
h	clock-hour-of-am-pm (1-	number	12
	12)		
Н	hour-of-day (0-23)	number	0
m	minute-of-hour	number	30
S	second-of-minute	number	55

Other classes

☐ **ZoneId** specifies a time zone identifier and provides rules for converting

Greenwich/UTC, without a time zone ID.

Standard Datatypes vs. Objects

Java treats standard data types (also called as primitive types) and objects of classes differently.

Standard data types are allocated memory on **stack**. Parameters of primitive type are always **passed by value.**

```
public void f1() {
   int a = 10, b = 20;

   f2(a, b);
}

public void f2(int x, int y) {
   int i = 1;
   x = 0;
}
Stack

i = 1

y = 20

x = 0

b = 20

a = 10
```

In the above picture, variable **a** and **b** are created on stack when control enters into **f1()**. When function **f2()** is called, **formal parameters x** and **y** are created and assigned values from **actual parameters** – **a** and **b**.

However, changes to ${\bf x}$ and ${\bf y}$ will not change ${\bf a}$ and ${\bf b}$ as they occupy different locations in memory.

NOTE: Passing parameters of standard data types is always pass-by-value.

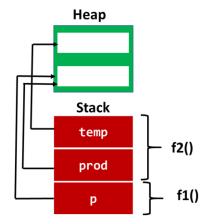

How objects are handled by Java?

Objects of classes are allocated memory dynamically on **heap** and they are released by garbage collector when they are not required.

Object is allocated memory on heap. However, an object reference is allocated memory on stack. When an object is passed to a function, only reference of the object is passed but not the object itself.

```
public void f1() {
   Product p;
        p = new Product(...);
        f2(p);
}

public void f2(Product prod) {
   Product temp;
        temp = new Product(...);
        prod.setPrice(1000);
}
```

NOTE: An object is always passed by reference.

In the above figure, object references **p** in **f1()** and **prod** in function **f2()** both refer to the same object. Object reference **temp** points to a new object.

When control comes out of **f2**(), object pointed by **temp** will be ready for garbage collection as it is no longer pointed by any object reference.

Wrapper Classes

Primitive types such as int and double are not objects in Java. Wrapper classes are used to convert primitive types to objects. Java provides a wrapper class for each primitive type (8 in total).

NOTE: Wrapper classes are declared as **final** and their values cannot be changed.

The following are the wrapper classes provided by Java and their corresponding primitive (standard) type.

Standard Type	Wrapper Class	Method to convert object to primitive type
boolean	Boolean	booleanValue()
byte	Byte	byteValue()
short	Short	shortValue()
int	Integer	intValue()
long	Long	longValue()
float	Float	floatValue()
double	Double	doubleValue()
char	Character	charValue()

Boxing and Unboxing

The following code shows how to use wrapper class Integer to convert an int to object (boxing) and back to int (unboxing).

```
01: int x =100;
02:    // convert int to an object
03:    Integer iobj = new Integer(x); // boxing
04:
05:    // get int from object
06:    x = iobj.intValue();    // unboxing
```

Autoboxing and Autounboxing

When a primitive data type is to be used as an object, it is to be **boxed** to an object of corresponding **wrapper** class. When the primitive value is to be taken from wrapper class object then the value is to be **unboxed** from object by using a method of wrapper class.

Starting from Java 5.0, Java does **boxing** and **unboxing** automatically. The following example shows how boxing and unboxing take place.

JSHELL

Also known as REPL (Read Evaluate Print Loop).
Used to execute any java code from command prompt.
Allows small code to be executed without having to create a class and main
method.
Start by entering jshell at command prompt.
We can give any Java statement or expression at jshell prompt (jshell>).
Results of expressions are stored in variable named as \$n where n is a number.
These variables are called as internal variables.
Code can be typed in multiple lines.
Commands of jshell start with / (slash). For example, /help and /exit.
It supports TAB for completion of expression.
It automatically imports some packages. We can get the list of packages
imported using /imports command.

Tab Completion

When entering snippets, commands, subcommands, command arguments, or command options, use the **Tab** key to automatically complete the item. If the item can't be determined from what was entered, then possible options are provided.

Command abbreviations

An abbreviation of a command is accepted if the abbreviation uniquely identifies a command.

History navigation

A history of what was entered is maintained across sessions. Use the *up* and *down* arrows to scroll through commands and snippets from the current and past sessions.

History search

Use the *Ctrl+R* key combination to search the history for the string entered. The prompt changes to show the string and the match. Ctrl+R searches backwards from the current location in the history through earlier entries. *Ctrl+S* searches forward from the current location in the history through later entries.

Command	Meaning	
/drop	Drops a snippet	
/edit	Opens an editor	
/exit	Exits jshell	
/history	Displays what was entered in this session	
/help	Displays information about commands and subjects	
/imports	Displays active imports	
/list	Displays list of snippets and their ID	
/methods	Lists methods that were created	
/open file	Opens the file and reads snippet into jshell. In place of file, you can	
	give DEFAULT, JAVASE or PRINTING.	
/reset	Resets the session	
/save file	Saves snippets and commands to the file specified	
/set	Sets configuration information	
/types	Displays types created in session	
/vars	Displays variables created in session	

Object Oriented Programming Part - 2

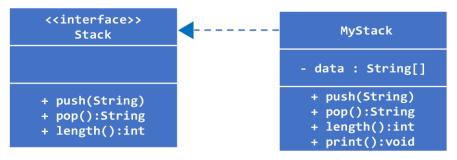

Interfaces

- An interface is a collection of methods that must be implemented by the implementing class.
- An interface defines a contract regarding what a class must do, without saying anything about how the class will do it.
- ☐ Interface can contain declaration of methods and variables.
- ☐ Implementing class must define all the methods declared in the interface.
- If a class implements an interface and does not implement all the methods then class itself must be declared as abstract.
- ☐ Variables in interface automatically become static and final variables of the implementing class.
- ☐ Members of interface are implicitly public, so need not be declared as public.

```
access interface name [ extends interface [,interface] ]
{
   returntype method([parameters]);
   datatype finalvariable = value;
}
```

NOTE: In UML, interface resembles a class. One way to differentiate an interface from a class is to use **<<interface>>>** stereotype as shown above.

The following example shows how to declare an interface and how a class implements the interface.

```
interface Stack {
    void push(String value);
    String pop();
    int length();
}
```

Stack is a data structure that stores data in such a way that last value pushed is first value to be popped (LIFO).

Implementing an Interface

The following class - **MyStack**, implements **Stack** interface and provides definition for methods in the interface. It also adds a new method – print() to print all values in the stack.

```
01: class MyStack implements Stack {
        private String data[] = new String[10];
02:
03:
        private int top = 0;
        public void push(String value) {
04:
            data[top] = value;
05:
06:
            top++;
07:
        public String pop() {
08:
09:
            top --;
10:
            return data[top];
11:
12:
        public int length() {
13:
            return top;
14:
        public void print() {
15:
            for (int i = 0; i < top; i ++) {
16:
17:
                 System.out.println(data[i]);
18:
            }
        }
19:
20: }
```

The following main() creates an object of MyStack class and calls its methods.

```
class UseMyStack {
01:
       public static void main(String[] args) {
02:
03:
          MyStack ms = new MyStack();
          ms.push("First");
04:
          ms.push("Second");
05:
          ms.print();
06:
07:
          System.out.println(ms.pop());
08:
       }
09: }
```

NOTE: A class can neither narrow the accessibility of an interface method nor specify new exceptions in the method's *throws* clause. For example, a method declared in interface cannot be overridden with any access narrower than public as it is implicitly declared as public in interface.

Using object reference of an Interface

An object reference of an interface can refer to an object of its implementing class or any subclass of implementing class.

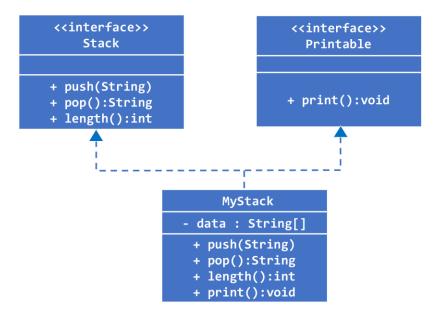

For example, an object reference of **Stack** interface can refer to an object of **MyStack** class as it implements Stack interface. However, only methods that are present in the interface can be called using object reference of interface even though the reference refers to object of implementing class.

The following code snippet shows how to use object reference of Stack interface.

```
Stack s;
s = new MyStack();
s.push("10");
System.out.println(s.pop());
// Cannot call print() as it is NOT a method of interface
Stack
s.print();
```

NOTE: An object reference of an interface can reference an object of implementing class. However, only methods in interface can be called using object reference of interface.

A single class can implement multiple interfaces. *Multiple inheritance* is supported using interfaces.

```
interface Printable {
    void print();
}
class MyStack implements Stack, Printable {
    ...
}
```

An Interface extending another

- ☐ An interface can extend **one or more** interfaces.
- A class implementing the interface must define all the methods in the entire inheritance chain.
- ☐ The interface being extended is called as *superinterface* and the one extending is called as *subinterface*.

```
interface A {
   void m1();
}
interface B extends A {
   void m2();
}
class c1 implements B {
   // implements both m1 and m2
}
```

Default Methods in Interface

- ☐ Default methods enable you to add new functionality to the interfaces and ensure binary compatibility with code written for older versions of those interfaces.
- ☐ You specify that a method definition in an interface is default with the **default** keyword at the beginning of the method signature.
- All method declarations in an interface, including default methods, are implicitly public, so you can omit the public modifier.
- ☐ When you extend an interface that contains a default method, you can do the following:
 - ✓ Not mention the default method at all, which lets your extended interface inherit the default method.
 - ✓ Redeclare the default method, which makes it abstract.
 - ✓ Redefine the default method, which overrides it.

Static Methods in Interface

You can define static methods in interfaces using static keyword.
 You can keep static methods specific to an interface, in the same interface rather than in a separate class.
 Static methods of interface can be called using interface name followed by method name. Ex. Counter.printAuthor()
 To call static method we don't need any implementation of interface or inheritance.

```
public interface Counter {
01:
02:
          void increment();
03:
          void decrement();
04:
          int getValue();
          default int getIncrement() {
05:
               return 1;
06:
07:
          static void printAuthor() {
08:
09:
              System.out.println("Srikanth Pragada");
10:
          }
11: }
```

```
public class OneCounter implements Counter {
01:
02:
        private int value;
03:
        @Override
        public void increment() {
04:
            value += getIncrement();
05:
06:
07:
        @Override
08:
        public void decrement() {
            value -= getIncrement();
09:
10:
        @Override
11:
12:
        public int getValue() {
            return value;
13:
14:
15: }
```

143

```
public class TenCounter implements Counter {
01:
02:
        private int value;
03:
        @Override
        public void increment() {
04:
           value += getIncrement();
05:
06:
07:
        @Override
        public void decrement() {
08:
           value -= getIncrement();
09:
10:
11:
        // Override default implementation
12:
        @Override
13:
        public int getIncrement() {
14:
            return 10;
15:
16:
        @Override
        public int getValue() {
17:
18:
           return value;
19:
        }
20:
```

```
01: public class TestCounter {
        public static void main(String[] args) {
02:
03:
           Counter.printAuthor();
04:
05:
           Counter c = new OneCounter();
06:
           c.increment():
           System.out.println(c.getIncrement());
07:
           System.out.println(c.getValue());
08:
09:
           c = new TenCounter();
10:
11:
           c.increment();
           System.out.println(c.getValue());
12:
13:
        }
14:
```

Functional Interface

- ☐ An interface that contains only one abstract method is called as functional interface.
- ☐ Functional interface can have default methods, but must have only one abstract method.
- ☐ An interface can be explicitly marked as functional interface using @FunctionalInterface annotation. However, the compiler will treat any interface meeting the definition of a functional interface as a functional interface regardless of whether or not a FunctionalInterface annotation is present on the interface declaration.
- ☐ Instances of functional interfaces can be created with lambda expressions, method references, or constructor references.
- ☐ Examples are **Runnable**, **Comparable** and **Comparator**.

```
01: @FunctionalInterface
02: public interface Printable {
03:     void print(String mgs);
04:     default String newline() {
05:        return "\n";
06:     }
07: }
```

Abstract Class vs. Interface

- Both interface and abstract class cannot have objects, but can have object references.
- ☐ In case of interface, object reference can reference an object of implementing class. An object reference of abstract class can reference an object of subclass.
- ☐ However, abstract class can have instance variables, but interface cannot have instance variables.

Null Interface

☐ Java allows interfaces to be empty. An empty interface contains no variables and methods. It is used to tag or mark a class as having certain property or behavior.

- ☐ For example, **Serializable** interface is a null interface.
- □ Null interface is also known as **marker interface**.

Private Methods in Interface

- ☐ Interface can have private methods that can be called from other methods of the interface.
- ☐ Private methods in interface cannot be called from implementing class.
- Provides more reusability in interfaces as these private methods can be called from other default methods.
- ☐ Must be declared with **private** keyword and must contain body.

```
01: public interface Logger {
     private void log(String message, String target) {
02:
         // log message to target
03:
04:
     }
05:
06:
     default void logToFile(String message) {
         log(message, "file");
07:
08:
     }
09:
     default void logToDatabase(String message) {
10:
11:
         log(message, "database");
12:
     }
13: }
```

146

Nested Classes

Nested class is a class defined in another class. Nested class may be any one of the following types:

Java SE Course Material

- ☐ Static member class
- Non-static member class
- Method-local inner class
- Anonymous inner class

Static member Class

A class created in another class with static modifier is called as static member class. It can be used just like a normal class.

However, to access it from outside of enclosing class, we have to use the name of enclosing class as the prefix for static member class.

```
01: // Top level class
02: class TLC {
     // static member class
03:
    static public class SMC {
04:
         public void print() {
05:
              System.out.println("SMC");
06:
07:
         }
08:
      public void print() {
09:
10:
         System.out.println("TLC");
11:
      }
12:
    public class TLCClient {
13:
14:
      public static void main(String ... args) {
         TLC.SMC srec = new TLC.SMC();
15:
16:
         srec.print();
17:
      }
18:
```

Non-static member class (inner class)

A class defined within another class without static modifier is called as non-static member class. It is also called as inner class.

Inner class has access to all of the variables and methods of its outer class and can refer to them directly. Inner classes were introduced in version 1.1 of Java, mainly to help handling events in AWT and Swing applications.

```
01: class OuterClass {
     private int m1 = 10;
02:
03:
     class InnerClass {
        private int m2 = 20;
04:
        public void print() {
05:
06:
          System.out.printf("m1 = %d, m2 = %d", m1, m2);
07:
08:
     }
09:
     public void print() {
10:
        InnerClass obj = new InnerClass();
11:
        obj.print();
12:
    }
13: }
14: public class InnerTest {
15:
        public static void main(String args[]) {
           OuterClass obj = new OuterClass();
16:
           obj.print();
17:
18:
19: }
```

```
m1 =10, m2 =20
```

Method-local Inner Class

A class declared inside a method is called as local class. Only the method, in which the class is defined, can create an instance of the class.

Just like any other inner class, a local inner class can access members of its outer class directly.

```
01: class TLC {
     private int v = 10;
02:
03:
     public void somemethod() {
04:
    class LocalClass {
05:
96:
       public void print() {
        System.out.printf("Local class.
07:
                            Outer class value %d\n", v);
08:
09:
10:
     }
   // use class here
11:
12:
    LocalClass obj = new LocalClass();
13: obj.print();
14: } // end of method
15: } // end of TLC
16:
17: public class LocalTest {
      public static void main(String[] args) {
18:
        TLC obj = new TLC();
19:
        obj.somemethod();
20:
21:
     }
22: }
```

Local class. Outer class value 10

Anonymous Inner Class

Anonymous inner class combines the process of defining an inner class and creating an object of inner class into one step. It is a class without any name (anonymous).

```
new <superclass or interface> (optional arguments) {
   Members definition
}
```

The optional arguments are passed to constructor of super class.

Anonymous class can extend either a class or implement an interface. No **extends** or **implements** keyword is required. The name given after keyword **new** is taken as class or interface.

If anonymous class implements an interface, then no arguments are passed as interfaces do not have constructor.

NOTE: Anonymous classes cannot have any constructors as they don't have a name.

```
01: interface Task {
02:
      void process();
03:
04:
    public class AnonymousDemo {
05:
      public static void main(String[] args) {
06:
07:
08:
         Task task = new Task() {
09:
              public void process() {
                System.out.println("Do the process!");
10:
11:
12:
         };
13:
         task.process();
14:
      }
15:
16:
```

Packages

- ☐ Package is a collection of classes and interfaces.
- Package allows you to store your classes and interface without name collision as two packages may have same names for classes and interfaces.
- ☐ Packages are stored in hierarchical manner. A package may be nested in another package. For example, java.util, java.lang etc. In java.util, util is a package that is in another package java.
- ☐ A package is a *folder* in the underlying operating system.

NOTE: All the classes that are not explicitly stored in any package are stored in **default package** or unnamed package, which is the current directory. And these classes are accessed directly without any package prefix.

Creating a Package and placing a Class in it

- ☐ Use **package** statement to specify the package to which classes and interfaces belong to.
- ☐ The package statement is applied to all classes and interfaces in the source file.
- A folder, in the file system of Operating System, with the same name as the package is to be created.
- ☐ The .class file must be stored in the package (directory).
- Once a class is placed in a package, it must always be accessed using package name as prefix packagename.classname.

package <fully qualified package name>

The following example shows how to create a class in a package called **library**. The package **library** must be created by creating a folder with that name.

```
01: package library; //Book class belongs to library package
02: public class Book {
03:    // class code
04: }
```

NOTE: If **package** statement is used then it must be the first statement in the source file.

Class **Book** belongs to package **library**. Apart from using package statement in .java file (as shown above), **Book**.class must be placed in folder **library** to make **Book** class belong to library package.

NOTE: A class with **public** access may be accessed from outside package, whereas a class with **default** access (no access) is confined to package in which it is defined.

If you want two public classes to belong to the same package then each class must be placed in a different .java file as shown below.

```
01: // Book.java
02: package library;
03: public class Book {
04:    // body of Book class
05: }
```

```
01: // Member.java
02: package library;
03: public class Member {
04:    // body of Member class
05: }
```

Accessing Classes of a Package

You can access a member of the package by using package name followed by dot (.). A member of the package must be prefixed with package name. The following code shows how to access Book class of library package.

```
01: public class UseLibrary {
02:    public static void main(String[] args) {
03:        library.Book b = new library.Book();
04:    }
05: }
```

The hierarchy of folders is as follows:

A package can be accessed only from its parent directory (unless CLASSPATH is used). In the above example, package library can be accessed only from **programs** folder.

Import Statement

Use **import** statement to import specified classes or packages into current source file.

import pkg1[.pkg2...].{classname|*}

* means all classes of the package are to be imported, but it does not import subpackages of the package.

NOTE: The **import** statement must be given after **package** statement in the source file if both exist.

The following examples import all members of package st, Date class in java.util package and all classes of java.text package.

```
import st.*;
import java.util.Date;
import java.text.*;
```

NOTE: Importing a package only imports classes in the package, but not nested packages in the package. So, classes in each nested package are to be explicitly imported.

NOTE: Package java.lang is automatically imported. So, its classes like String, System, Integer etc. can be used without importing them.

CLASSPATH variable

Contains the list of directories where Java will look for classes and packages.
Java compiler and runtime use CLASSPATH variable to get the list of folders and
.jar files that are to be searched for the required classes and packages.
By default, java searches for the specified classes in the current directory and in
standard library.
But once CLASSPATH is set then Java uses only the directories in CLASSPATH
and standard library to search for classes and does NOT search in the current
directory

The following example sets CLASSPATH to current directory (.) and c:\jdk\srikanth folder.

c:>set classpath=.;c:\jdk\srikanth

SET command is an operating system command. **CLASSPATH** is a variable used by Java compiler and JVM to locate packages and classes.

JAR (Java Archive) File

A JAR file contains packages, classes and interfaces. By including .jar file in CLASSPATH we can make its packages, classes and interfaces available to Java.

JAR utility, which is provided with JDK, is used to create and extract JAR files. This tool is invoked from command prompt.

The following command creates a JAR file to contain all .class files in library folder. Flag $\bf c$ stands for create, $\bf f$ stands for file and $\bf v$ stands for verbose.

C:\jdk\srikanth>jar cfv library.jar library*.class

You can see the content of a JAR file by using flag t (table of content) as follows:

c:\jdk\srikanth>jar ft library.jar

You need not extract JAR file to use its packages and classes. Just including .jar file in CLASSPATH will do.

So, to use **library.jar** that is placed in **c:\java** folder, we need to set classpath as follows:

c:>set classpath=.;c:\jdk\srikanth;c:\java\library.jar

Access Modifiers

Access modifiers specify from where a member can be accessed. The following are the available access modifiers for members of a class and their meaning.

Access Modifier	Meaning
private	Allows member to be accessed only from the class in which it
	is defined.
protected	Allows member to be accessed from the class and all its
	subclasses and also from any class in the same package.
default	Allows member to be accessed throughout the package to
	which the class belongs. If no access modifier is given then
	Java uses default as access modifier.
public	Allows a member to be accessed from anywhere.

NOTE: For top level classes, only **public** and **default** access modifiers are applicable. However, inner classes can have **private** and **protected** modifiers also.

The following example demonstrates how access modifiers influence the access of members from subclasses, other classes in the same package and other packages.

The following table summarizes access methods and their impact.

Where	Private	Default	Protected	Public
Same class	Yes	Yes	Yes	Yes
Subclass in same package	No	Yes	Yes	Yes
Non subclass in same package	No	Yes	Yes	Yes
Subclass in different package	No	No	Yes	Yes
Non-subclass in different package	No	No	No	Yes

A.java

B.java

D.java

```
01: package p2;
02: import p1.A;
03: public class D extends A {
     public void print() {
04:
05:
       // can access v2,v3
06:
07: }
08: class E {
     public void print() {
09:
       A obj = new A();
10:
11:
       // can access v3 of obj only
12:
     }
13: }
```

Static Import

- ☐ It allows static members of a class to be imported.
- Once the static members are imported, they may be used without qualification.
- ☐ Fully qualified name of the members must be used in import static statement.
- ☐ Should be used sparingly, otherwise causes loss of readability.

```
01: import static java.lang.Math.PI;
02: import static java.lang.Math.abs;
03: import static java.lang.System.out;
04:
05: public class StaticImport {
06:    public static void main(String[] args) {
07:        out.println (PI);
08:        out.println (abs(-100));
09:    }
10: }
```

Enumeration

- ☐ Enumeration is a collection of constants. Java provides support for enumeration through keyword enum.
- ☐ An **enum** is internally converted to a full-fledged class.
- □ Values in enumeration can be compared and assigned.
- ☐ Enumeration can be used with switch statement and enhanced for loop.

```
01: enum Languages {
02:
      C, CPP, JAVA, CSHARP
03: };
04: public class EnumDemo {
      public static void main(String[] args) {
05:
06:
            Languages lang;
07:
08:
            lang = Languages.JAVA;
            if (lang == Languages.JAVA)
09:
                   System.out.println("Next is Java EE");
10:
            System.out.println("Value of lang = " + lang);
11:
            switch (lang) {
12:
            case C:
13:
                   System.out.println("Java or C++");
14.
15:
                   break:
16:
            case CPP:
                   System.out.println("Java");
17:
18:
                   break;
19:
            case JAVA:
                   System.out.println("Java EE");
20:
21:
                   break:
            case CSHARP:
22:
23:
                   System.out.println("ASP.NET");
24:
                   break;
25:
26:
      } // end of main
27:
   } // end of class
```

Next is Java EE Value of lang = JAVA Java EE 162

Exception Handling

- An Exception is an abnormal condition (runtime error).
 When an exceptional event occurs, Java throws an exception.
- ☐ An exception is an object of a class that is created from **java.lang.Exception** class.
- ☐ Depending upon the error (exceptional event), an object of exception class is created and thrown.
- ☐ If the exception is not handled then program is terminated abnormally.
- Exception can be thrown by Java Runtime System or by the code.

The following code demonstrates what happens when you run code that throws an exception.

```
public class Test {
01:
        public static void main(String[] args) {
02:
03:
        int n;
04:
          n = Integer.parseInt(args[0]);
05:
          if (99 % n == 0) {
06:
07:
             System.out.printf("%d is a factor of 99", n);
08:
          }
09:
        }
10:
```

If the above program is run with a command line parameter that cannot be converted to int (such as *abc*) then exception **NumberFormatException** is thrown.

```
java Test abc
Exception in thread "main" java.lang.NumberFormatException:
For input string: "ABC" at
java.lang.NumberFormatException.forInputString(Unknown
Source) ...
```

When an exception is thrown, program is terminated at the line that caused the exception.

The following are the keywords related to exception handling in Java.

Keyword	Meaning
try	Specifies the block in which you want to monitor for exceptions.
catch	Catches an exception and takes necessary action.
finally	Contains the code that must be executed before leaving try block.
throws	Specifies the exceptions that a method might throw.
throw	Throws the given exception.

The following is the general syntax for try, catch and finally blocks.

```
try {
    // try block
}
catch(<exceptiontype> <parameter>) {
    // catch block
}
finally {
    // finally block
}
```

NOTE: After try block either catch or finally or both may be given. But you cannot avoid both.

Handling exception using try and catch

If you want to handle the exception that is likely to be thrown then place the code in **try** block and handle the exception in **catch** block as shown below.

```
public class Test {
01:
02:
     public static void main(String[] args) {
03:
      int n;
04:
      try{
          n = Integer.parseInt(args[0]);
05:
          if (99 \% n == 0)
06:
            System.out.printf("%d is a factor of 99", n);
07:
08:
09:
      catch (NumberFormatException ex) {
          System.out.println("Invalid number!");
10:
11:
12:
     } // end of main
13: } // end of class
```

Handling multiple exceptions

It is also possible to handle more than one exception. If the code in **try** block is likely to throw more than one exception then you have to handle all potential exceptions using multiple catch blocks.

However, note that a try block can throw only one exception at a time. Because once an exception is thrown, the code after the statement causing the exception will not be executed.

The following code shows how to handle two exceptions – *NumberFormatException* and *ArrayIndexOutOfBoundsException*.

```
01:
    public class Test {
02:
      public static void main(String[] args) {
03:
       int n;
04:
        try{
05:
          n = Integer.parseInt(args[0]);
          if (99 \% n == 0)
96:
              System.out.printf("%d is a factor of 99", n);
07:
08:
        }
        catch (NumberFormatException ex) {
09:
          System.out.println("Invalid number!");
10:
11:
        catch (ArrayIndexOutOfBoundsException ex) {
12:
13:
          System.out.println("Number parameter is missing");
14:
15:
      }
16:
```

In the code above, try block will throw *ArrayIndexOutOfBoundsException* if no parameter is passed on command line (as args[0] is not available). The other exception that will be thrown if string in args[0] cannot be converted to an integer is *NumberFormatException*.

166

Multi-Catch

Prior to Java 7, we had to catch only one exception type in each catch block. So whenever we needed to handle more than one specific exception, but take the same action for all exceptions, then we had to have more than one catch block containing the same code.

In the following code, we have to handle two different exceptions, but take the same action for both. So, we need two different catch blocks as of Java 6.0.

```
try {
   int v = Integer.parseInt(num);
   int result = 100 / v;
   System.out.println(result);
}
catch (NumberFormatException ex) {
   // take action
}
catch (ArithmeticException ex) {
   // take action
}
```

Starting from Java 7.0, it is possible for a single catch block to catch multiple exceptions by separating exception with | (pipe) symbol in catch block.

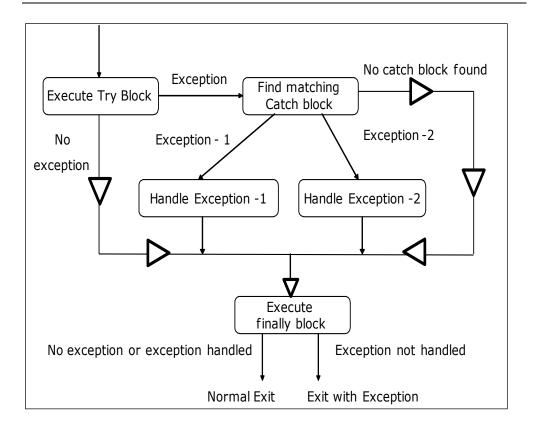

```
try {
    int v = Integer.parseInt(num);
    int result = 100 / v;
    System.out.println(result);
}
// multi-catch
catch (NumberFormatException | ArithmeticException ex) {
    // take action
}
```

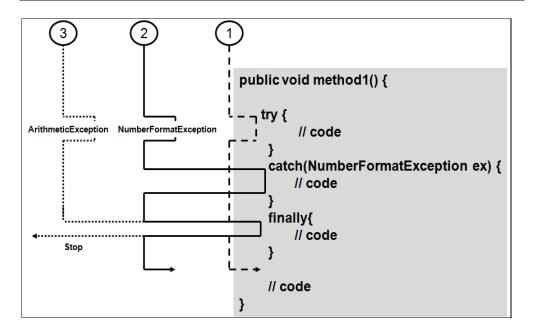

A catch block that handles multiple exception types creates no duplication in the bytecode generated by the compiler; the bytecode has no replication of exception handlers.

The finally block

- ☐ Used to execute code that is to be executed after a try/catch block has completed and before the code following try/catch is executed.
- ☐ Can be used to perform any operation that must be done before you leave try/catch block clean up code.
- ☐ The **finally** clause is optional. If it is given, it must be given either after catch block(s), if it exists, or after try block.

```
try {
    // code
}
finally {
    // code
}
```

The following snippet demonstrates how to use finally block.

```
public void m1() {
  try {
     // code
  }
  catch(NumberFormatException ex) {
     // exception code
  }
  finally {
     // place cleanup code
  }
}
```

The following are the cases in which the finally block in the above snippet is executed:

- ☐ When try block is successfully executed without any exceptions then control goes to finally block after try block.
- ☐ When *NumberFormatException* is thrown in try block, the exception is handled by catch block and then control goes to finally block.
- ☐ When try block throws an uncaught exception then also control goes to finally block and then program is terminated. But in this case the program is terminated after finally block is executed.

Run the code below and see the output (shown below) to understand flow of control with try, catch and finally blocks.

```
01: public class FinallyTest {
        public static void main(String[] args) {
02:
           method("5");
03:
           method("abc");
04:
           method("0");
05:
06:
        } // end of main()
07:
08:
        public static void method(String value){
09:
         try {
10:
           int n = Integer.parseInt(value);
11:
           System.out.println(100 / n);
12:
         catch(NumberFormatException ex) {
13:
           System.out.println("Invalid number!");
14:
15:
         finally {
16:
           System.out.println("Finally block.");
17:
18:
         }
19:
         System.out.println("**Method Completed**");
20:
        } // end of method()
21:
22: }
```

Exception may be thrown by JVM or by methods in classes (API). In the above program *NumberFormatException* is thrown by **parseInt**() of *Integer* class, which is Java API.

Exceptions ArithmeticException and ArrayIndexOutOfBoundsException are thrown by JVM.

Types of Exceptions – checked and unchecked

There are two types of exceptions - Unchecked or Implicit exceptions and Checked or Explicit exceptions.

Unchecked Exceptions

Handling unchecked exceptions is not mandatory. Some of these exceptions are thrown by JVM and others by Java API. However, you may want to handle unchecked exceptions to prevent program from getting terminated and handle exceptional events.

All exceptions that extend **RuntimeException** class are unchecked exceptions.

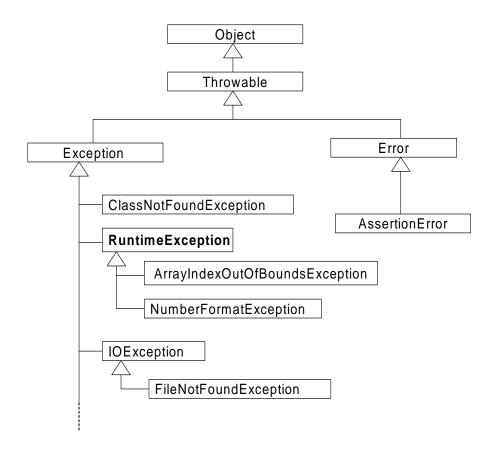

Checked Exceptions

Checked exceptions are thrown by methods. These exceptions must be handled by the code calling the method using try and catch blocks.

In method declaration, we have to specify the checked exceptions that the method is likely to throw using **throws** clause.

Methods that might throw a checked exception must be called from try block where catch block handles the checked exception. Or the calling method must declare checked exception that might be thrown by called method in its **throws** clause.

NOTE: Checked exceptions are always thrown from methods and never by JVM.

The following code snippet shows how to handle or propagate checked exceptions.

```
public class TestChecked {
01:
        public void m1() throws AmountException {
02:
03:
          // code
04:
05:
        public void m2() throws AmountException {
06:
          m1();
07:
        public void m3() {
08:
          try {
09:
10:
             m1();
11:
          catch(AmountException ex){
12:
13:
14:
       }
15:
```

The following are the points related to above program:

- ☐ Method m1() is likely to throw a checked exception, **AmountException**, and it must be handled by methods calling m1().
- ☐ Method m2() compiles even though it calls m1() without handling AmountException as it declares **AmountException** in its throws clause.
- ☐ Method m3() handles **AmountException** that is likely to be thrown by m1() using try and catch blocks.

Invalid vs. Valid order of catch blocks

Understanding the hierarchy of exception classes is important. Most specific exception must be handled first and then less specific.

The following snippet shows invalid order for exception handling and will result in compilation error.

```
try{
    ...
}
catch(Exception ex) { }
catch(RuntimeException ex) { }
catch(NumberFormatException ex) { }
```

Any exception is a match to *Exception* class. So giving catch block with Exception class first will not allow other catch blocks to ever get control and makes those catch blocks unreachable.

Valid order of catch blocks

The following is valid order of catch blocks. Most specific exception – *NumberFormatException* is handled first and most general, *Exception*, is handled last.

```
try{
    ...
}
catch(NumberFormatException ex){ }
catch(RuntimeException ex){ }
catch(Exception ex) { }
```

Creating user-defined exception

It is possible to create a new exception by creating a class. User-defined exceptions can be thrown and caught just like ready-made exceptions. However, unlike JVM exceptions, which are thrown by Java Runtime, user-defined exceptions are to be explicitly thrown by methods.

To create a user-defined exception, create a class that extends **Exception** class directly or indirectly.

The exception class need not create any method of its own since it inherits methods of **Exception** class. The following code shows how to create a user-defined exception and how to throw and catch.

```
01: class StackFullException extends Exception {
       public StackFullException()
02:
         super("Stack is full"); // exception message
03:
04:
       }
05:
06: class Stack {
       public void push(int v) throws StackFullException {
07:
         if(condition)
08:
               throw new StackFullException();
09:
10:
       }
11:
```

User-defined exception *StackFullException* will be thrown by **push** method in case of an error. Any code calling **push** method must make sure it catches *StackFullException* as it is given in **throws** clause of push method. The following snippet shows how to handle push method.

```
try {
    s.push(10);
    ...
}
catch(StackFullException ex) {
    System.out.println (ex.getMessage());
}
```

Exception class

The following are the methods available in *Exception* class. In fact, all these methods are actually derived from *Throwable* class and *Exception* class has no methods of its own.

Method	Meaning
getMessage()	Returns description of the exception. The message is passed to Exception class by its subclass using constructor of Exception class.
printStackTrace()	Displays the stack trace providing all methods that are invoked from the beginning to the point of error.

User-defined exceptions example

Here is a complete example to demonstrate creating, throwing and handling user-defined exceptions using Account class.

```
01: public class InvalidAmountException extends Exception {
02:    public InvalidAmountException() {
03:        super("Invalid Transaction Amount!");
04:    }
05:    public InvalidAmountException(String msg) {
06:        super(msg);
07:    }
08: }
```

```
public class InsufficientAmountException
01:
                                  extends Exception {
02:
        public InsufficientAmountException() {
03:
04:
            super("Insufficient Balance!");
05:
06:
        public InsufficientAmountException(String msg) {
07:
            super(msg);
08:
        }
09: }
```

```
public class Account {
01:
02:
     String acno;
03:
     double balance:
     public Account(String acno, double balance) {
04:
       this.acno = acno:
05:
       this.balance = balance;
96:
07:
     public void deposit(double amount)
08:
                        throws InvalidAmountException {
09:
10:
       if (amount < 100) {
11.
           throw new InvalidAmountException();
12:
13:
       balance += amount;
14:
     public void withdraw(double amount) throws
15:
16:
         InvalidAmountException, InsufficientAmountException{
17:
       if (amount < 100) {
18:
             throw new InvalidAmountException();
19:
       if (balance < amount) {</pre>
20:
             throw new InsufficientAmountException();
21:
22:
       balance -= amount;
23:
24:
25: }
```

```
public class UseAccount {
01:
        public static void main(String[] args) {
02:
           Account a = new Account("1002", 10000);
03:
04:
           try {
05:
               a.deposit(1000);
               System.out.println("Deposited 1000");
06:
                a.deposit(50);
07:
08:
           catch(InvalidAmountException ex) {
09:
               System.out.println(ex.getMessage());
10:
11:
           try {
12:
13:
                a.withdraw(5000);
               System.out.println("Withdrew 5000");
14:
               a.withdraw(8000);
15:
               System.out.println("Withdrew 8000");
16:
17:
           catch(Exception ex) {
18:
19:
               ex.printStackTrace();
20:
           }
21:
22: }
```

```
Deposited 1000
Invalid Transaction Amount!
Withdrew 5000
InsufficientAmountException: Insufficient Balance!
at Account.withdraw(Account.java:26)
at UseAccount.main(UseAccount.java:24)
```

180

Assertions

- Assertions can be used to validate assumptions made about state of the program.
- ☐ Each assertion is associated with a Boolean condition. If condition fails it means the assumption fails and assertion error occurs.
- Assertions are **disabled** by default. So, you must enable assertions at the time of running program.
- Assertions are part of development process. They should not be included in final version of your code.

```
assert <boolean expression>
assert <boolean expression> : message
```

When boolean expression results in false, Java throws **AssertionError**. If it results in true, execution of program continues normally.

If message is given then it is displayed in stack trace when assertion error occurs. The following code shows how to use assertion to validate parameter of a private method.

```
public class AssertionTest {
01:
02:
        private void print(int count) {
03:
            assert count > 0: "Invalid count for print()";
04:
        }
05:
06:
07:
        public static void main(String[] args) {
            AssertionTest t = new AssertionTest();
08:
09:
            t.print(1);
10:
            t.print(0);
        }
11:
12: }
```

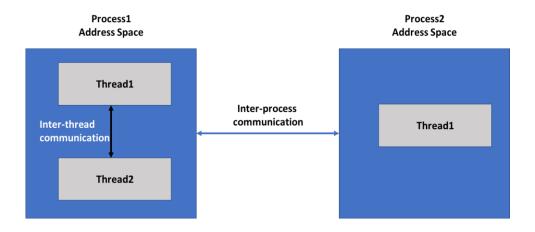

If you run the previous program by enabling assertions using **–ea** flag of JVM as shown below then the following will result:

```
>java -ea AssertionTest
Exception in thread "main" java.lang.AssertionError: Invalid
count for print()
...
```

NOTE: Assertions must be used in such a way that, even though assertions are disabled, the functionality of the program does not change. And also remember assertions are only debugging aids.

Multithreading

- ☐ An independent sequential path of execution within a program is called as a thread.
- ☐ When a program contains two or more parts that run concurrently, it is called as multithreading.
- ☐ Java's libraries are designed with multithreading on mind.
- ☐ Each thread is also called as lightweight process and the overheads are low compared with a process.
- A thread may exist in any of the states such as running, ready, blocked etc., during its life time.
- ☐ All the threads of a process run within the same address space.
- ☐ Context switching between threads is less expensive and faster than context switch between processes.
- ☐ Thread object in Java represents a thread.

Process

- ☐ A process has a self-contained execution environment.
- A process generally has a complete, private set of basic run-time resources; in particular, each process has its own memory space.
- ☐ Processes are often seen as synonymous with programs or applications.
- ☐ Most implementations of the Java virtual machine run as a single process.

Main Thread

- ☐ Main thread is the first thread to start in a Java program.
- ☐ This is the thread from where other threads are created and started.
- ☐ It is typically the last thread to terminate. When main thread terminates then the program terminates unless other threads spawned by main thread still run.
- ☐ This thread is created by JVM to run main() method.

```
01: public class MainThread {
02:    public static void main(String[] args) {
03:         Thread t = Thread.currentThread();
04:
05:         System.out.println(t.getName());
06:         System.out.println(t.getPriority());
07:    }
08: }
```

The following are two different ways in which a new thread can be created.

- By extending Thread class.
- ☐ By implementing interface **Runnable**.

Creating a new thread by extending Thread class

You can create a new thread by creating an object of a class that extends **Thread** class. The following are the steps to be followed:

- ✓ Create a class that extends Thread class.
- ✓ Override run () method of Thread class.
- Create an object of subclass of **Thread** class and invoke **start()** method to start running the thread, which in turn calls **run()** method.

```
01: // Multi-threading using subclass of Thread class
02: class ChildThread extends Thread {
03:
        @Override
        public void run()
04:
          for (int i = 1; i <= 50; i ++) {
05:
           System.out.println("Child -> " + i);
06:
07:
      } // end of run
08:
09: } // end of ChildThread
10:
11: public class MainThread {
       public static void main(String args[]){
12:
        System.out.println("In Main");
13:
        ChildThread ct1 = new ChildThread();
14:
        ct1.start(); // run thread
15:
16:
17:
        System.out.println("In Main again");
18:
        for (int i = 1; i <= 50; i ++) {
        System.out.println("Main -->" + i);
19:
        } // end of for
20:
21:
22:
        System.out.println("End of main");
       } // end of main()
23:
24:
```

Creating a new thread using Runnable interface

A new thread can be created by using an object of **Thread** class and a class that implements **Runnable** interface. Follow the steps below to create a thread:

- Create a class that implements Runnable interface.
- ☐ Implement run() method of Runnable interface.
- ☐ Create an object of **Thread** class and send an object of the class which implements Runnable interface as parameter to constructor of **Thread** class.
- ☐ Call **start**() method of **Thread** class. It then calls **run**() method of the object that is passed as parameter to constructor of **Thread** class.

NOTE: Runnable interface has a single **run()** method. **Thread** class also implements **Runnable** interface.

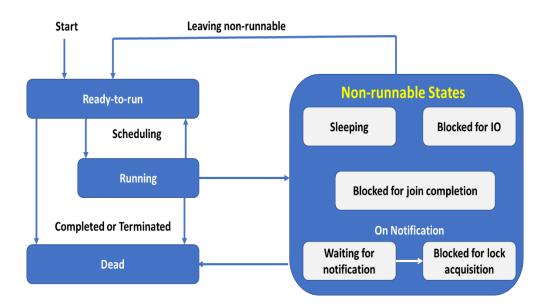

```
01: class ThreadCode implements Runnable {
02:
         public void run() {
           for (int i = 1; i <= 50; i ++) {
03:
               System.out.println(i);
04:
05:
96:
         } // end of run
07: } // end of ThreadCode
08:
09:
    public class RunnableThread {
     public static void main(String args[]) {
10:
       ThreadCode code = new ThreadCode();
11:
       Thread t = new Thread(code);
12:
13:
       t.start(); // Calls run() method of code object
14:
       for (int i = 1; i <= 50; i ++)
15:
          System.out.println("Main --> " + i);
16:
17:
      }
18: }
```

Thread States - life cycle of a thread

A thread can exist in different states at different points of time. A thread passes from one state to another state since it is started using **start()** method.

The following table and figure discuss different states and the transitions in the life cycle of a thread.

State	Meaning				
New	A new thread object is created and not yet started.				
Ready to run	Thread is started using start () method. In this state, thread				
	is ready to run, but control is not given. If control is given				
	then it starts running. Apart from being in this state in the				
	beginning, a thread enters into this state from other states				
	as well.				
Running	Thread is currently running.				
Sleep	Method sleep () is invoked and thread is sleeping for the				
	given number of milliseconds.				
Blocked for IO	Thread has initiated some IO operation and is waiting for				
	completion of the operation.				
Blocked for join	Thread awaits completion of another thread.				
Waiting for	Thread awaits notification from another thread. Thread				
notification	has executed wait() method of an object. It will wait until				
	another thread invokes notify () or notifyAll () method of				
	that object on which it invoked wait (). This is related to				
	inter-thread communication.				
Blocked for lock	Thread waits to acquire the lock of an object. Once a				
acquisition	thread is notified by another thread, it will wait until it can				
	acquire lock on an object. This is related to inter-thread				
	communication.				
Dead	Thread is terminated.				

Thread priority

- ☐ Each thread is associated with a priority.
- Priority is used by thread scheduler to decide which of the available threads should be given control.
- Priority is relative and not absolute. That means the priority of other thread will decide whether current thread gets control.
- ☐ Use **setPriority**(int) and **getPriority**() methods to set and get priority of a thread.
- ☐ Thread class has three static members (MIN_PRIORITY, NORM_PRIORITY, MAX_PRIORITY), which can be used to set priority of the thread.
- Default priority of a thread is normal priority, which is represented as number5.
- ☐ A thread inherits priority of its parent thread.

Thread class

Thread class is used to create a new thread. Every thread in Java is an object of Thread class. Thread class provides static and non-static methods that perform operations on threads.

static int MAX_PRIORITY	The maximum priority that a thread can have.
static int MIN_PRIORITY	The minimum priority that a thread can have.
static int NORM_PRIORITY	The default priority that is assigned to a thread.

```
Thread()
Thread(Runnable target)
Thread(Runnable target, String name)
Thread(String name)
```

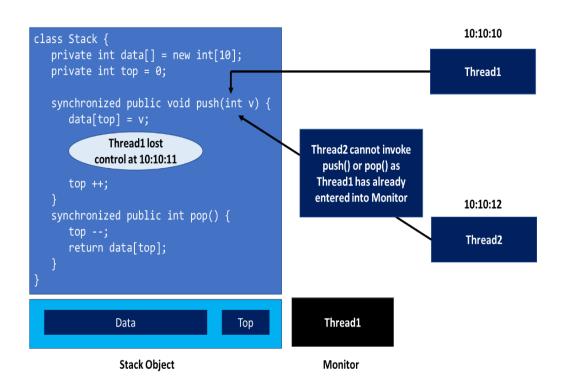

Method	Meaning			
static Thread	Returns a reference to the currently executing			
currentThread()	thread object.			
void destroy()	Destroys this thread, without any cleanup.			
String getName()	Returns this thread's name.			
int getPriority()	Returns this thread's priority.			
void interrupt()	Interrupts this thread.			
boolean isAlive()	Tests if this thread is alive.			
boolean isDaemon()	Tests if this thread is a daemon thread.			
void join()	Waits for this thread to die.			
void join(long millis)	Waits at most millis milliseconds for this thread to			
	die.			
void run()	Specifies the code to be executed. It is overridden			
	by subclass of Thread class.			
void setDaemon	Marks this thread as either a daemon thread or a			
(boolean on)	user thread. Must be done before thread is started.			
void	Changes the name of this thread to be equal to the			
setName(String name)	argument name.			
void	Changes the priority of this thread.			
setPriority(int priority)				
static void	Causes the currently executing thread to sleep			
sleep(long millis)	(temporarily cease execution) for the specified			
	number of milliseconds.			
void start()	Causes this thread to begin execution. The Java			
	Virtual Machine calls the run method of this thread.			
static void yield()	Causes the currently executing thread object to			
	temporarily pause and allow other threads to			
	execute.			

```
class DaemonThread extends Thread {
01:
02:
         public void run() {
03:
04:
             // code
05:
         }
06: }
07:
08: class ThreadMethods {
      public static void main(String args[]) {
09:
        System.out.println("waiting...");
10:
11:
        try {
          Thread.sleep(1000); // will wait for 1000 MS
12:
13:
          // do something
14:
        catch (InterruptedException ex) {
15:
        }
16:
        // make a thread a daemon
17:
        DaemonThread dt = new DaemonThread();
18:
19:
        dt.setDaemon(true);
        dt.start(); // starts daemon
20:
21:
22:
        ChildThread ct = new ChildThread();
        ct.start();
23:
24:
        try {
25:
          ct.join(); // current thread waits till ct is dead
          System.out.println("Child completed");
26:
27:
28:
        catch(InterruptedException ex) {
29:
      }
30:
31: }
```

Synchronization

☐ This is the process by which Java ensures that a shared resource is accessed only by one thread at a time.

- ☐ Java provides synchronization as part of language using synchronized methods and synchronized statements.
- A monitor is an object that is used as a mutually exclusive lock, or *mutex*. Only one thread can enter into a monitor at a given time. When a thread acquires a lock, it is said to have entered the monitor.
- When a thread invokes a synchronized method, it locks the object (enters the monitor) preventing other threads from invoking any synchronized method of the object.

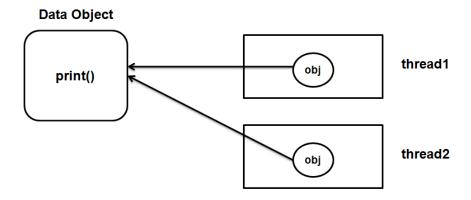

The scenario shown by above figure is as follows:

- ☐ Thread1 and Thread2 both access the same object of Stack class.
- ☐ At 10:10:10 Thread1 called **push()** method of stack object.
- By calling **push()** method, which is synchronized, Thread1 entered into monitor of stack object. It means stack object is now locked.
- After executing first statement in **push()** method, at 10:10:11 Thread1 lost control and control is given to Thread2.
- Upon receiving control, Thread2 tries to enter into **push()** method at 10:10:12, but cannot enter into it as the monitor of stack object still has Thread1.

NOTE: To enter into any synchronized method of an object, a thread must first enter into monitor of the object. Object of the class that has at least one synchronized method is associated with a monitor.

The following example shows importance of synchronizing a method when two or more threads are accessing the same object.

```
01: class Data {
      synchronized public void print() {
02:
         for(int i = 1; i <= 5; i ++) {
03:
04:
           System.out.println(i);
           try {
05:
06:
             Thread.sleep(100);
07:
08:
           catch(Exception ex) {}
09:
         }
10:
   } // end of data
11:
12:
13: class CThread extends Thread {
14:
       Data obj;
       public CThread (Data obj) {
15:
16:
         this.obj = obj;
17:
18:
       public void run() {
19:
         obj.print();
20:
21:
   } // end of CThread
22:
23: public class SyncTest {
     public static void main (String args[]) {
24:
25:
        CThread thread1, thread2;
26:
        Data obi = new Data();
        // make two threads access the same object
27:
28:
       thread1 = new CThread(obj);
29:
       thread2 = new CThread(obj);
       thread1.start();
30:
31:
       thread2.start():
32: } // end of main
33:
```

Synchronized statement

Synchronized statement allows you to implement synchronization even when you cannot make a method synchronized. This is required when you have to synchronize a method in a class whose source code is available to you (only .class file is available).

```
synchronized (object) {
  // invoke methods to be synchronized
}
```

The **object** used with synchronized statement is the object whose methods are to be synchronized. Synchronized block ensures that a call to a method, which is a member of object used with synchronized statement, occurs only after the current thread has successfully entered object's monitor.

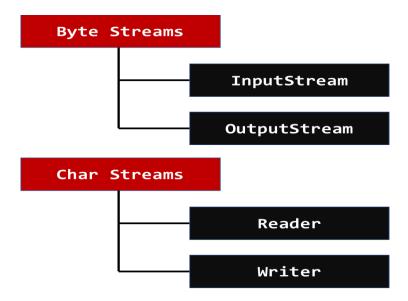

Change **run()** method of **CThread** class as follows to use synchronization. The rest of the program remains same as shown in the previous case.

```
01: class CThread extends Thread {
02:
03:    public void run(){
04:         synchronized(obj) {
05:         obj.print();
06:      }
07:    }
08: } // end of CThread
```

Java Library Part - 2

In	put-Output Streams
	A stream is an ordered sequence of bytes of undetermined length.
	An input stream moves data from external source and output stream sends data to external target.
	A stream that is linked to a file on the disk or printer or a network connection behaves in the same manner irrespective of the differences between the devices it is connected to.
	All classes and interfaces related to IO Streams are in java.io and java.nio packages.
By	yte Streams
	Treat the stream as a collection of bytes.
	Used when data that is input or output is to be treated as bytes.
	All byte streams are derived from either InputStream or OutputStream.
Cl	naracter Streams
	Treat the stream as a collection of characters.
	They use Unicode and therefore, can be internationalized

☐ At the top of the hierarchy there are two abstract classes – **Reader** and **Writer**.

Predefined Streams

- □ System class of java.lang package contains three static variables in, out and err.
- ☐ **System.out** refers to standard output stream, which is console by default.
- ☐ **System.in** refers to standard input stream, which is keyboard by default.
- ☐ **System.err** refers to standard error stream, which is console by default.
- ☐ System.in is of type InputStream.
- ☐ System.out and System.err are objects of type PrintStream.

Reader Class

Reader is an **abstract** class in **java.io** package. This class provides most fundamental methods related to reading data from a text stream.

Method	Meaning			
int read()	Reads a character. Returns -1 on EOF. It returns			
	Unicode of the character.			
int read(char buf[])	Reads characters into the array. Returns the number of			
	bytes read. But buf may not be filled completely, if			
	end-of-file is encountered before the array is filled.			
long skip(long n)	Skips the specified number of characters.			
void close()	Closes the stream.			
boolean	Returns true if stream supports mark operation. Used			
markSupported()	to check whether stream supports marking.			
void mark	Mark the present position in the stream.			
(int readAheadLimit)	Parameter readaheadlimit specifies the number of			
	characters that may be read while still preserving the			
	mark.			
void reset()	If the stream has been marked, it attempts to			
	reposition it at the mark.			

FileReader Class

- FileReader class is a subclass of InputStreamReader class, which is subclass of Reader class. Its constructor takes name of the file to be opened.
- ☐ It is used to read characters from a file. File may be given either as a string or as an object of **File** class.

```
FileReader(File file)
FileReader(String fileName)
```

The following program takes filename from user and displays its content on the screen.

```
01: import java.io.FileReader;
02: import java.util.Scanner;
03:
04: public class ReadFile {
05:
     public static void main(String args[]){
06:
      try {
07:
       Scanner s = new Scanner(System.in);
       System.out.println("Enter filename :");
08:
       String filename = s.nextLine();
09:
       FileReader fr = new FileReader(filename);
10:
11:
       int ch; // must be an int as read() returns int
12:
       while (true) {
13:
          ch = fr.read();
14:
          if (ch == -1) break;
          System.out.print((char)ch);
15:
16:
       fr.close();
17:
18:
19:
      catch(Exception ex) {
20:
       System.out.println(ex.getMessage());
21:
22:
     } // end of main
   } // end of class
23:
```

Exercise: Count number of words in a given file.

BufferedReader Class

It improves performance by buffering characters to provide efficient reading of
characters.

- ☐ It is derived from **Reader** class.
- ☐ Buffer size may be specified using parameter to constructor or default size may be used.

BufferedReader(Reader in)
BufferedReader(Reader in, int buffersize)

readLine() method

It reads a line of text from the Reader provided as parameter to constructor. A line is considered to be terminated by linefeed (ASCII code 10) or carriage return (ASCII code 13) or by both.

It returns null on end-of-file (EOF).

```
import java.io.*;
01:
02:
   public class LineRead {
     public static void main(String...args) throws Exception{
03:
04:
      FileReader fr = new FileReader("c:\\names.txt");
05:
      BufferedReader br = new BufferedReader(fr);
06:
07:
      String line;
08:
      line = br.readLine();
09:
      while(line !=null)
10:
11:
        System.out.println(line);
        line = br.readLine();
12:
13:
   br.close();
14:
15:
   fr.close();
    } // end of main
16:
17: } // end of class
```

Exercise: Accept a filename, a string and display all lines in the file that contain the given string.

InputStreamReader Class

- ☐ This class is used as a bridge between byte stream and character stream.
- ☐ It reads data from InputStream, which is passed as parameter to its constructor, and provides them in the form of characters as it is derived from Reader class.

InputStreamReader(InputStream source)

It can be used to convert **System.in**, which is of type **InputStream**, as a **Reader**. Once System.in is converted to Reader, it can be passed to **BufferedReader** to read one line at a time.

```
// read a line from keyboard
Reader r = new InputStreamReader (System.in);
BufferedReader br = new BufferedReader(r);
String line = br.readLine();
```

NOTE: InputStreamReader is a subclass of Reader class. So, an object of InputStreamReader can be passed wherever a Reader is expected.

LineNumberReader Class

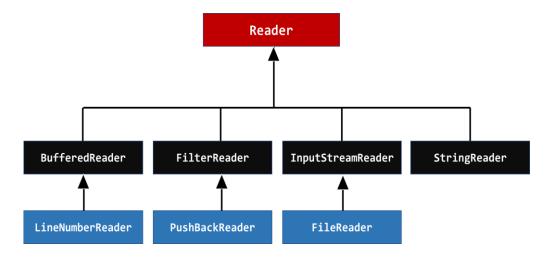

This class extends **BufferedReader** and provides methods to get and set line numbers.

```
LineNumberReader(Reader)
int getLineNumber()
void setLineNumber(int)
```

Exercise: Display only non-blank lines of the given file along with line numbers.

Hierarchy of Reader Classes

The following is the hierarchy of Reader and its subclasses.

PushbackReader Class - Unread char

- ☐ This class allows you to push back a character after reading it from the stream.
- ☐ This is a **FilterReader**, which provides additional functionality to base stream from where it takes data.

PushbackReader(Reader)

void unread(int c)

Automatic Resource Management (ARM)

- Resources are closed by Java automatically calling **close**() method at the end of try block.
- ☐ This feature is also called as **try-with-resources**.
- ☐ Generally, closing of a resource is done explicitly in finally block.
- Any resource used with ARM must implement **AutoCloseable** interface and define **close()** method, which is the only method in the interface, so that Java invokes that method

```
try (resources creation) {
    // process resource
}
catch(..) {
    // handle exceptions
}
```

Try with resource can now use a resource that is already declared outside the Try-With-Resource Statement as final or effectively final.

```
resource = create resource
try (resource)
{
    // process resource
}
catch(..) {
    // handle exceptions
}
```

```
Scanner s = new Scanner(System.in);
try(s) {
   // code
}
```

Writer Class

This is an abstract class for writing characters to a stream. It allows either writing individual characters or strings. But while writing strings you have to write new line (\n) character explicitly.

Method	Meaning			
void close() Closes the stream, flushing it first.				
void flush()	lush() Writes pending data to stream.			
void write(int c)	Writes a single character.			
void write(String str)	Writes a string.			

In order to improve the performance of writing, data written to a stream from the program is first held in a **buffer** and then the content of the buffer is written to stream.

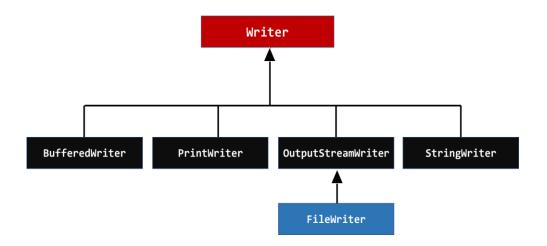

The following are the cases in which the buffer is written to strear	The	following	are the	cases in	which	the	buffer	is	written	to	strear	n:
--	-----	-----------	---------	----------	-------	-----	--------	----	---------	----	--------	----

- When buffer is filled.
- ☐ When stream is closed.
- ☐ When **flush**() method is called.

206

Hierarchy of Writer Classes

The following diagram shows hierarchy of Writer and its subclasses.

FileWriter Class

- ☐ Used to write characters to a stream that is connected to a file.
- ☐ **FileWriter** is derived from **OutputStreamWriter**, which is derived from **Writer**.

```
FileWriter(File file)
FileWriter(File file, boolean append)
FileWriter(String fileName)
FileWriter(String fileName, boolean append)
```

If **append** is true, then output is added to the end of the file.

The following program reads data from source file and writes it into target file after converting each line to uppercase.

```
01:import java.io.*;
02:import java.util.Scanner;
03:public class ConvertToUpper {
04:
      public static void main(String[] args) {
05:
         Scanner s = new Scanner(System.in);
         System.out.println("Enter source filename :");
06:
         String srcfile = s.nextLine();
07:
         System.out.println("Enter target filename :");
08:
         String trgfile = s.nextLine();
09:
10:
11:
         try (FileReader fr = new FileReader(srcfile);
            FileWriter fw = new FileWriter(trgfile)) {
12:
            BufferedReader br = new BufferedReader(fr);
13:
            String line;
14:
            while(true) {
15:
              line = br.readLine();
16:
              if(line == null)
17:
18:
                    break;
              fw.write(line.toUpperCase() + "\n");
19:
20:
21:
22:
         catch (Exception ex) {
            ex.printStackTrace();
23:
24:
         }
      }
25:
26:}
```

PrintWriter Class

- Prints the given data after formatting it to a text-output stream. This class implements all the print methods found in **PrintStream**.
- ☐ Methods in this class never throw I/O exceptions. The client may inquire as to whether any errors have occurred by invoking **checkError**() method.

```
PrintWriter(OutputStream out)
PrintWriter(OutputStream out, boolean autoFlush)
PrintWriter(Writer out)
PrintWriter(Writer out, boolean autoFlush)
```

AutoFlush parameter specifies whether output is to be automatically flushed when a newline (\n) character is written.

Method	Meaning
void print(value)	Prints the given value to the stream.
void println(value)	Prints the given value along with new line.

RandomAccessFile Class

beginning of the file.

Represents random access file, where you can read and write data from
anywhere in the stream.
RandomAccessFile writes data in binary format. When you write an integer, it
writes the memory image of integer as-it-is into file. So, it writes 4 bytes for an
integer, irrespective of the actual value.
Implements DataInput and DataOutput interfaces, which contain methods to
read and write primitive types from and to stream.

☐ Allows pointer to be placed at a specific position using offset (in bytes) from the

RandomAccessFile (String name, String mode)
RandomAccessFile (File obj, String mode)

Mode may be either "r" for reading or "rw" for read and write.

Method	Meaning				
long length()	Returns the length of this file.				
type read <type>()</type>	Reads the specified value. <type> is one of the</type>				
	primitive types such as int, long etc.				
void seek(long pos)	Sets the pointer to the specified location. The pos is				
	number of bytes from the beginning of the file.				
void write <type>(value)</type>	Writes the specified value. <type> is one of the</type>				
	primitive types.				

The following example shows how to use random access file to write an array of integers into a file and then read the numbers randomly.

```
01: import java.io.RandomAccessFile;
02: public class RandomAccessDemo {
     public static void main(String[] args)
03:
             throws Exception {
04:
     int phonenumbers[]={1111111, 2222222, 3333333, 4444444};
05:
     RandomAccessFile raf = new RandomAccessFile
06:
                    ("c:\\java\\numbers.dat","rw");
07:
08:
     // write numbers into file
    for(int n : phonenumbers)
09:
        raf.writeInt(n);
10:
11:
     // read numbers from file
     raf.seek(0); // start at the beginning
12:
     int count =(int) raf.length() / 4;
13:
14:
15:
     for(int i = 0; i < count; i ++)
        System.out.println(raf.readInt());
16:
17:
     // modify a number in the file
18:
     raf.seek(2 * 4); // go to third number
19:
     raf.writeInt(9999999); // write new number
20:
21:
22:
     // display numbers once again
23: raf.seek(0);
24:
     for(int i = 0; i < count; i ++)
        System.out.println(raf.readInt());
25:
26:
     }
27: }
```

File Class

	Represents a	file or	directory	in	file system
--	--------------	---------	-----------	----	-------------

- ☐ The file or directory may not be present physically.
- ☐ Provides methods to get information about the absolute pathname.
- ☐ Contains methods to create, delete, and rename files and directories.

File(String pathname)
File(String parent, String child)
File(File parent, String child)

Constructor is used to create a new **File** instance by converting the given pathname or parent and child names into an abstract pathname.

Method	Meaning
boolean canRead()	Tests whether the application can read the file.
boolean canWrite()	Tests whether the application can modify the file.
boolean	Automatically creates a new, empty file named by this
createNewFile()	abstract pathname, if and only if a file with this name
	does not yet exist.
boolean delete()	Deletes the file or directory denoted by this abstract
	pathname.
boolean exists()	Tests whether the file denoted by this abstract
	pathname exists.
String	Returns the absolute pathname.
getAbsolutePath()	
String getName()	Returns the name of the file or directory.
String getParent()	Returns the pathname string of this abstract
	pathname's parent, or null if this pathname does not
	name a parent directory.
boolean isAbsolute()	Tests whether this abstract pathname is absolute.
boolean isDirectory()	Tests whether the pathname is a directory.
boolean isFile()	Tests whether the pathname is a normal file.
boolean isHidden()	Tests whether the file is a hidden file.
long lastModified()	Returns the time that the file was last modified.

long length()	Returns the length of the file denoted by pathname.
File[] listFiles()	Returns an array of pathnames denoting the files in
	the directory.
boolean mkdir()	Creates the directory named by the pathname.
boolean	Renames the file denoted by this abstract pathname.
renameTo(File dest)	
long getTotalSpace()	Returns total size in bytes for the given drive or
	partition.
long getUsableSpace()	Returns the number of bytes available in the given
	partition or drive.

Exercise: Accept path from user and display list of files from the given path.

Files Class

☐ It consists exclusively of static methods that operate on files, directories, or other types of files.

☐ It is part of **java.nio.file** package.

Path copy(Path source, Path target, CopyOption options) void delete(Path path) boolean deleteIfExists(Path path) boolean isDirectory(Path path, LinkOption options) Stream <string> lines(Path path) Path move(Path source, Path target, CopyOption options) Stream<path> Reads all lines from a file as a Stream. long size(Path nath) Peturns the size of a file (in bytes)		it.
long size(Fath path) Neturns the size of a file (in bytes).	long size(Path path)	Returns the size of a file (in bytes).
Path walkFileTree(Path start, Walks a file tree.	Path walkFileTree(Path start,	Walks a file tree.
FileVisitor super Path visitor)	FileVisitor super Path visitor)	

Path writeString(Path path, String text,	Writes a CharSequence to a file.
Charset cs)	
Stream <path> walk(Path start)</path>	Returns a Stream that is lazily
	populated with Path by walking the file
	tree from start.

Path interface

A Path object represents a path that is hierarchical and composed of a sequence of directory and file name elements separated by a special separator or delimiter.

Method	Description
Path getFileName()	Returns the name of the file or directory
	denoted by this path as a Path object.
FileSystem getFileSystem()	Returns the file system that created this object.
Path getName(int index)	Returns a name element of this path as a Path
	object.
int getNameCount()	Returns the number of name elements in the
	path.
Path getParent()	Returns the parent path, or null if this path
	does not have a parent.
Iterator <path>iterator()</path>	Returns an iterator over the name elements of
	this path.
Path toAbsolutePath()	Returns a Path object representing the
	absolute path of this path.
File toFile()	Returns a File object representing this path.
URI toUri()	Returns a URI to represent this path.

Static Method	Description
Path of (String first, String more)	Returns a Path by converting a path string, or a sequence of strings that when joined form a path string.
	path string.
Path of(URI uri)	Returns a Path by converting a URI.

Paths Class

This class consists exclusively of static methods that return a Path by converting a path string or URI.

Method	Meaning
Path get (String first,	Converts a path string, or a sequence of strings that when
String more)	joined form a path string, to a Path.
Path get(URI uri)	Converts the given URI to a Path object.

Removing blank lines from a File

The following program is used to remove blank lines from a file. At the end of the process, the given source file should not have any blank lines. In order to achieve that, we adopt the following algorithm:

Open source file using BufferedReader.
Create a temporary target file using FileWriter.
Read a line from source file. If it is not blank line then write it into target file.
At the end, close both source and target files.
Move target file to source file.

```
01: import java.io.*;
02: import java.nio.file.*;
03: import java.util.Scanner;
04:
05: public class RemoveBlankLines {
06:
     public static void main(String[]args) throws Exception{
        Scanner s = new Scanner(System.in);
07:
08:
        System.out.println("Enter Source Filename : ");
        String srcfile = s.nextLine():
09:
        Path src = Paths.get(srcfile);
10:
11:
        BufferedReader br = Files.newBufferedReader(src);
12:
13:
        Path trg = Paths.get("tempfile.txt");
14:
        BufferedWriter bw=Files.newBufferedWriter
15:
                            (trg. StandardOpenOption.CREATE):
16:
        while(true) {
          String line = br.readLine();
17:
          if(line == null)
18:
            break;
19:
           if(line.length() > 0)
20:
                                      // non blank line
            bw.write(line + "\n");
21:
22:
        }
23:
        bw.close();
24:
        br.close();
        Files.move(trg, src,
25:
                   StandardCopyOption.REPLACE_EXISTING);
26:
27:
        s.close();
28:
      }
29: }
```

Serialization

Serialization is the process of writing the state of an object (values of instance
variables) to a byte stream.

- Serialization allows object data to be stored on disk and later retrieved using deserialization process.
- ☐ Serialization is also used in distributed applications to send and receive object data across network from one system to another for example it is used in RMI (Remote Method Invocation).

Serializable Interface

In order to serialize an object of a class, the class must implement **Serializable** interface. Serializable is a null interface — an interface with no methods. By implementing Serializable interface, a class informs to Java that objects of the class can be serialized.

ObjectOutput and ObjectInput Interfaces

ObjectOutput interface extends **DataOutput** interface and supports object serialization by providing **writeObject()** method.

ObjectInput interface extends **DataInput** interface and supports object describilization using **readObject()** method.

ObjectOutputStream and ObjectInputStream Classes

ObjectOutputStream class implements ObjectOutput interface and extends OutputStream class.

ObjectInputStream class implements ObjectInput interface and extends InputStream class.

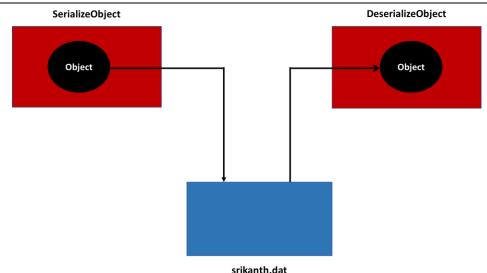

The following are the constructors of these classes:

ObjectOutputStream (OutputStream)
ObjectInputStream (InputStream)

OutputStream is the stream to which object data is to be written and InputStream is the stream from where object data is to be read.

```
01: import java.io.Serializable;
02: class Person implements Serializable {
      private String name, email;
03:
      public Person(String name, String email) {
04:
05:
        this.name = name;
        this.email = email;
06:
07:
08:
      public String toString() {
        return name + "," + email;
09:
      }
10:
11: }
```

```
01: import java.io.*;
02: public class SerializeObject {
03:
     public static void main(String ...args) {
      Person p=new Person("Sri", "sri@gmail.com");
04:
     try(FileOutputStream output =
05:
                new FileOutputStream("srikanth.dat")) {
06:
07:
          ObjectOutputStream outstream =
                new ObjectOutputStream(output);
08:
09:
          outstream.writeObject(p);
10:
      }
      catch(Exception ex){
11:
          System.out.println(ex);
12:
13:
      }
14:
15:
```

```
01: import java.io.FileInputStream;
02: import java.io.ObjectInputStream;
03: public class DeserializeObject {
      public static void main(String[] args){
04:
05:
          // deserialize the object
06:
          try (FileInputStream input =
              new FileInputStream("srikanth.dat")) {
07:
              ObjectInputStream instream =
08:
                       new ObjectInputStream(input);
09:
              // read object from stream and cast to Person
10:
              Person p = (Person) instream.readObject();
11:
12:
              System.out.println(p.toString());
13:
14:
          catch(Exception ex){
              System.out.println(ex);
15:
16:
          }
      }
17:
18:
```

Char Streams vs. Byte Streams

The following table shows character streams and their corresponding byte streams.

Character Stream	Byte Stream
Reader	InputStream
Writer	OutputStream
FileReader	FileInputStream
FileWriter	FileOutputStream
BufferedReader	BufferedInputStream
BufferedWriter	BufferedOutputStream
PrintWriter	PrintStream
FilterReader	FilterInputStream
LineNumberReader	LineNumberInputStream
PushbackReader	PushbackInputStream

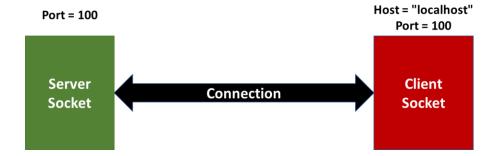

Networking

- ☐ Java provides classes which allow you to program internet or TCP/IP network.
- ☐ All classes are made available through **java.net** package.
- ☐ Data transfer between Java programs, running on different systems, is done using IO streams.
- ☐ Server can use multi-threading to handle multiple clients at the same time.

Socket programming

- ☐ Sockets enable communication between two programs running in the same JVM or different JVMs.
- Server socket is associated with a number called **port** number.
- ☐ In order to access a server socket, client socket has to provide the name of machine on which server socket runs and the port number at which server socket listens.
- ☐ Port number is an integer to uniquely identify each server socket on a system.

 Name of the system and port number uniquely identify a server socket in a network.
- Once you establish a connection with socket, you can take **InputStream** to read data from socket and **OutputStream** to write data to socket.

The following table shows some of the common internet applications and their port numbers.

Port	Application/Protocol
21	File Transfer Protocol (FTP)
23	Telnet Protocol
25	Simple Mail Transfer Protocol (SMTP)
80	Hypertext Transfer Protocol (HTTP)
110	Post office protocol (POP3)

Socket Class

- Socket class represents a client socket. A client socket connects to a server socket, which is created using **ServerSocket** class.
- ☐ Connect to a server socket by specifying the name of the computer and port number of server socket.
- Address of server is specified either by using IP address or the name of the computer.

Socket(InetAddress address, int port)
<u>Socket(String host</u>, int port)

Method	Meaning
void close()	Closes this socket.
InetAddress getInetAddress()	Returns the address of the machine to which
	the socket is connected.
InputStream getInputStream()	Returns an input stream for this socket.
OutputStream	Returns an output stream for this socket.
getOutputStream()	
int getPort()	Returns the remote port to which this socket
	is connected.

ServerSocket Class

- ☐ Creates a server socket with the given port number.
- ☐ A server socket waits for a request to come from clients and processes the requests.

```
ServerSocket(int port)
ServerSocket(int port, int qu<u>euelength)</u>
```

Port specifies the port number at which server socket listens.

Queuelength specifies the maximum number of clients that can wait while socket is busy.

Method	Meaning
Socket accept()	Waits for a request and returns client socket.
void close()	Closes this socket.
InetAddress getInetAddress()	Returns the local address of this server socket.
int getLocalPort()	Returns the port on which this socket is
	listening.

The following program creates a server socket that waits for a request to come from client and sends system date and time back to client.

```
01: import java.io.PrintWriter;
02: import java.net.*;
03: import java.util.Date;
04: public class TimeServer {
      public static void main(String args[])
05:
                                   throws Exception {
06:
        ServerSocket ss = new ServerSocket(2000);
07:
        System.out.println("TimeServer is ready...");
08:
        while (true) {
09:
           Socket cs = ss.accept(); // wait for client
10:
11:
           PrintWriter pw = new PrintWriter
                  (cs.getOutputStream(), true);
12:
           pw.println(new Date().toString()); //to client
13:
          } // end of while
14:
15:
        } // end of main
16: } // end of class
```

The following program connects to server socket - TimeServer - and then reads the data sent from server.

```
01: import java.io.InputStream;
02: import java.net.Socket;
03: import java.util.Scanner;
04: public class TimeClient {
     public static void main(String[]args) throws Exception{
05:
06:
07:
       // connect to server at port number 2000
       Socket cs = new Socket("localhost",2000);
08:
       // get stream to read data from server
09:
       InputStream is = cs.getInputStream();
10:
11:
       // Use Scanner to read a line
       Scanner scanner = new Scanner(is);
12:
13:
       String line = scanner.nextLine();
       System.out.println(line);
14:
15:
      }
16: }
```

InetAddress Class

- ☐ This class represents an IP address and domain name.
- ☐ InetAddress class has factory methods (static methods that return instance of the class) which return an object of InetAddress for the given name with the required details.
- ☐ Provides methods to get name and host address (IP address) of a system.

Method	Meaning
static InetAddress[]	Determines all the IP addresses of the given
getAllByName (String host)	host's name.
static InetAddress getByName	Determines the IP address of the given host
(String host)	name.
String getHostAddress()	Returns the IP address string "%d.%d.%d.%d".
String getHostName()	Returns the hostname for this address.
static InetAddress	Returns the local host.
getLocalHost()	

URL Class

- ☐ Represents a Uniform Resource Locator.
- ☐ URL is used to uniquely identify a resource in Internet or network.

```
URL(String spec)
URL(String protocol, String host, String file)
URL(String protocol, String host, int port, String file)
```

A URL contains the following components:

Protocol	It represents protocol used to access the resource. Common	
	protocols are HTTP, FTP, File etc. Default protocol is HTTP.	
Host	Name of the system. System may be referred either by name or	
	by IP address.	
Port number Port number of server socket to be accessed. If none is give		
	port number 80 (http) is taken.	
File	File to be accessed on the server. The path must be understood	
Specification	by the server processing the URL.	

The following are important methods of URL class:

Method	Meaning
boolean equals(Object obj)	Compares two URLs.
String getFile()	Returns the file name of this URL.
String getHost()	Returns the host name of this URL, if applicable.
int getPort()	Returns the port number of this URL.
String getProtocol()	Returns the protocol name of this URL.
URLConnection	Returns a URLConnection object that represents a
openConnection()	connection to the remote object referred to by the
	URL.
InputStream openStream()	Opens a connection to this URL and returns an
	InputStream.

The following is an example of a complete URL. It has the following components.

http://www.srikanthtechnologies.com:80/aboutus.aspx

The following program takes a URL and a filename from user and copies the content of the URL into the given file. It opens an input stream for given URL and reads one byte at a time and writes it into target file.

```
01:import java.net.*;
02:import java.io.*;
03:import java.util.Scanner;
04:class Download {
     public static void main(Stringargs[]) throws Exception{
05:
       Scanner s = new Scanner(System.in);
06:
       System.out.print("Enter URL : ");
07:
       String fromurl = s.nextLine();
08:
       System.out.print("Enter filename : ");
09:
       String filename = s.nextLine();
10:
       URL urlobj = new URL(fromurl);
11:
       InputStream is = urlobj.openStream();
12:
13:
       FileOutputStream fo = new FileOutputStream(filename);
       while(true){
14:
        int ch = is.read();
15:
        if(ch == -1)
16:
17:
            break;
         fo.write(ch);
18:
19:
20:
       fo.close();
21:
       is.close();
22:
     }
23:}
```

Collections Framework

Collections framework provides classes to implement useful data structures (such as linked list) and algorithms (such as sorting). The following are advantages of using Collections Framework:

Reduces programming effort by providing useful data structures like linked list
and hash table, and algorithms like searching and sorting, so that you don't
have to write them yourself. This saves a lot of programmer's time allowing
programmer to spend more time on business logic and rules.
Increases performance by providing high-performance implementations of
useful data structures and algorithms.
Reduces the effort required to learn APIs by eliminating the need to learn multiple ad hoc collection APIs.

The following are the core interfaces provided by Collections Framework and their implementing classes (concrete classes):

Interface	Meaning	Implementing classes
Collection	Provides basic operations required to a	
Cat	collection of objects.	Llash Cat
Set	Extends Collection and provides unique set of values.	HashSet
SortedSet	Extends Set and ensures elements are in sorted order.	TreeSet
List	Extends Collection and allows elements to be	ArrayList
	accessed by position.	Vector
		LinkedList
Мар	Provides method to maintain a collection of	HashMap
	pairs, where each pair contains a key and	HashTable
	value.	
SortedMap	Extends Map interface and ensures pairs are	TreeMap
	sorted on key.	
Queue	Extends Collection and adds methods to insert,	LinkedList
	extract and inspect.	PriorityQueue

Collection Interface

- ☐ This is the most basic interface. Contains methods to add, remove, search and iterate over list.
- ☐ Provides methods that collection related classes should provide.

Method	Meaning
boolean add(Object)	Adds an object to collection.
boolean addAll	Adds all elements of the collection.
(Collection col)	
void clear()	Clears all elements from the collection.
boolean contains	Returns true if the given object is found in the
(Object obj)	collection.
boolean containsAll	Returns true if all elements of parameter collection
(Collection col)	are present in the current collection.
boolean isEmpty()	Returns true if collection is empty.
Iterator iterator()	Returns an iterator, which is used to iterate over
	items of collection.
boolean remove	Removes the given object.
(Object obj)	
boolean removeAll	Removes all elements from the collection that are
(Collection col)	present in parameter collection.
boolean retainAll	Retains only the elements in the list that are in the
(Collection col)	parameter collection.
int size()	Returns number of elements.
Object [] toArray()	Returns an array containing all the elements of the
	collection.
boolean removeIf	Removes all elements that satisfy given predicate.
(Predicate)	
Stream <e> stream()</e>	Returns a sequential Stream.
Stream <e></e>	Returns a parallel Stream.
parallelStream()	

NOTE: Methods removeAll(), retainAll(), addAll() return true if source list is changed as the result of the operation, otherwise they return false.

NOTE: Though by default, parameters are of type Object for many methods, using generics, we can specify the type of objects the parameters must support.

List Interface

- ☐ An ordered collection (also known as a *sequence*).
- ☐ Allows elements to be accessed by their position (index).
- ☐ Classes ArrayList, LinkedList and Vector implement List interface.

Method	Meaning
void add(int index,	Inserts the given object at the specified
Object value)	position.
Object get(int index)	Returns object from the specified
	position in this list.
int indexOf(Object value)	Returns the index of the first occurrence
	of the specified object or -1 if object is
	not found.
ListIterator listIterator()	Returns a list iterator of the elements in
	this list.
Object set(int index, Object	Replaces the object at the specified
newvalue)	position with the new object.
void replaceAll(UnaryOperator <e>)</e>	Replaces each element of the list with
	the result of the operator.
void sort(Comparator)	Sorts the list according to order induced
	by Comparator.
List <e> subList(int from, int to)</e>	Returns a list between from (inclusive)
	and to (exclusive) elements.
Object remove(int index)	Removes element at the specified
	position.

ArrayList Class

- ☐ Implements **List** interface.
- ☐ Each **ArrayList** instance has a *capacity*. The capacity is the size of the array used to store the elements in the list. It is always at least as large as the list size. As elements are added to an *ArrayList*, its capacity grows automatically.
- One of the constructors allows you to specify initial capacity of the list.

```
ArrayList()
ArrayList(Collection c)
ArrayList(int initialCapacity)
```

NOTE: It is important for classes whose objects are used with collections to override equals() method.

```
01: import java.util.*;
    public class ArrayListDemo {
02:
03:
       public static void main(String args[]) {
04:
        ArrayList nl = new ArrayList();
        nl.add("Ronaldo");
05:
        nl.add("Messi");
06:
        nl.add("Modric");
07:
        nl.add(1,"Hazard");
08:
        // display the list
09:
        for (Object obj : n1)
10:
            System.out.println(obj);
11.
12:
        nl.remove("Ronaldo");
13:
        System.out.println(nl.indexOf("Messi"));
14:
15:
       }
16:
```

Generics

- ☐ Allow you to specify to compiler the type of object you want to store in a collection.
- ☐ Generics make collection classes type-safe by ensuring a collection supports only one type of objects.
- At the time of creating an object of a collection class, we can specify which type of objects the collection supports.
- ☐ Eliminates the need to typecast the object taken from collection makes it convenient and faster.

```
01: // Code without Generics
02: ArrayList al = new ArrayList();
03: al.add("First");
04: al.add(new Integer(100));
05: String st;
06: st = (String) al.get(0); // typecasting is required
07: System.out.println(st.toUpperCase());
08: st = (String) al.get(1); // results in Exception
```

In the above code, when you try to typecast *al.get(1)* to *String*, it results in **ClassCastException**, because *al.get(1)* actually refers to an object of type *Integer* and it cannot be converted to *String*.

235

The following example demonstrates how generics make collections type-safe and convenient to use.

```
01: // Code using Generics
02: ArrayList<String> al = new ArrayList<String>();
03: al.add("First");
04: // al.add(new Integer(100)); // compile-time error
05: al.add("Second");
06: String st;
07: st = al.get(0); // typecasting is NOT required
08: System.out.println(st.toUpperCase());
09: // can be used with enhanced for loop
10: for (String s : al)
11: System.out.println(s.toLowerCase());
```

Generics allow you to specify the type of object you want a data structure like **ArrayList** to support. Compiler checks whether objects used with ArrayList **al** are of type **String**. If any other type of object other than **String** is used with **al** then it is taken as a compile-time error.

Set Interface

- □ Set interface represents a collection that contains no duplicate elements.
 □ It extends Collection interface.
- ☐ This doesn't add any new methods to *Collection* interface. A class implementing Set interface must make sure the elements are unique.
- ☐ HashSet and LinkedHashSet classes implement Set interface.

HashSet Class

- ☐ Implements the **Set** interface.
- ☐ It does not guarantee the order of elements.

```
HashSet()
HashSet(Collection c)
```

NOTE: Class LinkedHashSet is same as HashSet except that it orders elements according to insertion order.

NOTE: For objects that are used with HastSet, LinkedHashSet and TreeSet, it is important to override hashCode() method.

The following program demonstrates usage of **LinkedHashSet**. It displays unique lines (ignoring duplicates) of a file.

```
01: import java.nio.file.Files;
02: import java.nio.file.Path;
03: import java.util.LinkedHashSet;
04:
05: public class UniqueLines {
     public static void main(String[]args) throws Exception{
96:
       Path path = Path.of("c:\\classroom\\names.txt");
07:
08:
       var lines = Files.readAllLines(path);
09:
       var uniqueLines = new LinkedHashSet<String>(lines);
10:
11:
        for (var line : uniqueLines)
         System.out.println(line);
12:
13:
    }
14:
```

SortedSet Interface

- ☐ SortedSet extends Set and ensures the elements are always in the ascending order.
- ☐ It provides the following methods to retrieve elements from first, last and subset from head, tail or middle.
- ☐ Class **TreeSet** implements **SortedSet** interface.

Method	Meaning
Object first()	Returns first value in the list.
Object last()	Returns last value in the list.
SortedSet headSet (Object	Returns a list consisting of values that are
toElement)	less than toElement.
SortedSet tailSet (Object	Returns a list consisting of values that are
fromElement)	greater than or equal to fromElement.
SortedSet subset (Object	Returns a list consisting of values that are
fromElement, Object toElement)	from fromElement, inclusive, to toElement,
	exclusive.

238

The following program is to display common lines (intersection) of two files.

```
01:import java.nio.file.Files;
02:import java.nio.file.Path;
03:import java.nio.file.StandardCopyOption;
04:import java.util.LinkedHashSet;
05:
06:public class IntersectFiles {
07: public static void main(String[]args) throws Exception{
     Path oldNamesPath=Path.of("c:\\classroom\\names.txt");
08:
     Path newNamesPath=Path.of("c:\\classroom\\names2.txt");
09:
     var oldNames = new LinkedHashSet<String>
10:
                    (Files.readAllLines(oldNamesPath));
11:
12:
     var commonNames = new LinkedHashSet<String>();
13:
     for(String name : Files.readAllLines(newNamesPath)) {
14:
          if (oldNames.contains(name))
              commonNames.add(name);
15:
16:
      for(String name : commonNames)
17:
          System.out.println(name);
18:
19:
      }
20:}
```

TreeSet Class

- ☐ This class implements **SortedSet** interface.
- ☐ It is based on balanced tree data structure.
- Objects being used must be comparable (by implementing **Comparable** interface, which contains **compareTo**() method).

TreeSet() TreeSet(Comparator)

It ensures objects are sorted according to natural order. In case, you specify *Comparator* (using second constructor), which is an object of a class that

implements **Comparator** interface, the objects are sorted according to order specified by *Comparator*.

```
01:import java.util.TreeSet;
02:class Person implements Comparable<Person>{
     private String name;
03:
04:
     private int age;
     public Person(String name, int age) {
05:
06:
    this.name = name;
    this.age = age;
07:
08:
     }
    public int compareTo(Person other) {
09:
      return this.name.compareTo(other.name);
10:
11:
     public String toString() {
12:
13:
    return name + " - " + age;
14:
     }
15:}
16:
17:public class SortPersons {
     public static void main(String args[]) {
18:
19:
     var people = new TreeSet<Person>();
20:
     people.add(new Person("Larry", 34));
21:
     people.add(new Person("Bill", 44));
22:
     people.add(new Person("Bill", 44));
23:
    people.add(new Person("Mark", 25));
24:
   for (var p : people)
25:
        System.out.println(p);
26:
27:
     }
28:}
```

Comparator<T> Interface

Comparator allows you to implement compare method so that program can specify the precise order for sorting.

int compare<T>(T o1, T o2)

The return value of **compare()** method must be one of the following.

Return value	What it means?
Zero (0)	Both the objects are equal.
Greater than 0 (> 0)	First object is greater than second object.
Less than 0 (< 0)	First object is less than second object.

Queue Interface

- ☐ This interface extends Collection interface and provides methods to add and retrieve values from queue.
- ☐ Classes **LinkedList** and **PriortyQueue** implement **Queue** interface.

Method	Meaning
Object element()	Retrieves, but does not remove, the head of the queue.
	Throws exception – NoSuchElementException – if queue
	is empty.
boolean offer (Object)	Inserts an element into queue, if possible.
Object poll()	Retrieves and removes the head of the queue or returns
	null if queue is empty.
Object remove()	Retrieves and removes the head of this queue. Throws
	exception if queue is empty.
Object peek()	Retrieves, but does not remove, the head of this queue,
	returns null if this queue is empty.

LinkedList Class

Doubly-Linked list implementation of the List interface.
Can be used as a stack, queue or double-ended queue (deque).
Starting from Java 5.0, it implements Queue interface also.

LinkedList() LinkedList(Collection c)

☐ This implementation is not synchronized.

Apart from methods in **List** and **Queue** interfaces, it provides the following extra methods.

Method	Meaning
void addFirst(Object o)	Inserts the given element at the beginning of the list.
void addLast(Object o)	Appends the given element to the end of this list.
Object getFirst()	Returns the first element of this list.
Object getLast()	Returns the last element of this list.
Object removeFirst()	Removes and returns the first element from this list.
Object removeLast()	Removes and returns the last element from this list.

NOTE: Class PriorityQueue implements Queue interface and orders elements by natural order. Elements of PriorityQueue must be comparable – implement Comparable interface, which contains compareTo() method.

Vector Class

- ☐ Vector is one of the legacy classes but recreated to implement **List** interface in version 1.2.
- ☐ It retained old methods of Vector class such as **addElement**() etc. and also provides methods of **List** interface.
- ☐ It is **synchronized**. It should be considered instead of ArrayList, if multiple threads use a single vector.

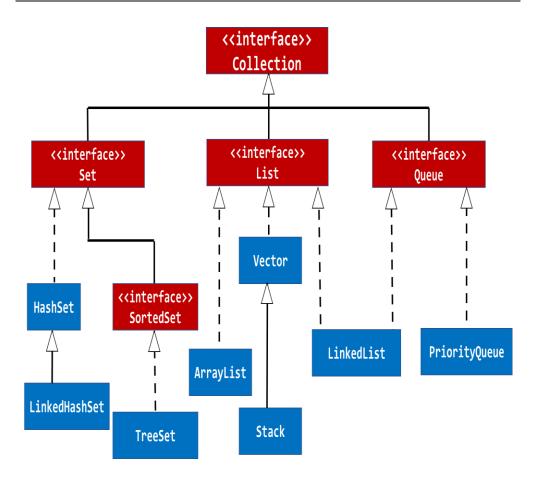

```
Vector()
Vector(Object[])
Vector(Collection)
```

Method	Meaning
void addElement(Object obj)	Adds the component at the end of the
	vector.
Object elementAt(int index)	Returns element at the given index.
void removeElementAt(int index)	Deletes the component at the specified
	index.
void insertElementAt	Inserts the specified object as a component
(Object obj, int index)	in this vector at the specified index.
void setElementAt	Sets the component at the specified index to
(Object obj, int index)	the specified object.
Enumeration elements()	Returns an enumeration of the elements.

Enumeration Interface

- ☐ Allows you to access elements of a **Vector**.
- ☐ New implementations should consider using Iterator instead of Enumeration.

Method	Meaning
boolean hasMoreElements()	Returns true if it contains more elements.
Object nextElement()	Returns the next element of this enumeration.

Stack Class

- ☐ Represents a last-in-first-out (LIFO) stack of objects.
- ☐ Extends **Vector** class and provides the following extra methods related to stack.

Method	Meaning
boolean empty()	Tests if this stack is empty.
Object peek()	Returns the object at the top of this stack without
	removing it.
Object pop()	Removes the object at the top of this stack and
	returns that object.
Object push(Object item)	Pushes an item onto the top of this stack.
int search(Object o)	Returns the 1-based position where an object is on
	this stack.

Exercise: Accept file name from user and display contents of file in reverse order - first line last.

Map Interface

- ☐ Allows keys to map values.
- ☐ A map does not allow duplicate keys. Each key can map to at most one value.
- ☐ HashMap and HashTable implement Map interface.

Method	Meaning
void clear()	Clears the map.
boolean containsKey(Object key)	Returns true if the given key exists.
Object get(Object key)	Returns the value of key.
boolean isEmpty()	Returns true if this map is empty.
Set keySet()	Returns a set view of the keys contained in
	this map.
Object put (Object key, Object	Places the key and the value.
value)	
Object remove (Object key)	Removes the mapping for this key from this
	map if present.
boolean remove	Removes value for the key if it contains the
(Object key, Object value)	given value.
int size()	Returns the number of keys.
Collection values()	Returns a collection view of the values
	contained in this map.
void forEach(BiConsumer <k,v>)</k,v>	Performs the given action for each element.
V getOrDefault	Returns the value for key or defaultValue if
(Object key, V defaultValue)	key not found.
V putIfAbsent(K key, V value)	If key is not associated with a value, then
	puts value and returns null, else returns
	current value.
V replace(K key, V value)	Replaces value of given key to value.
boolean replace	Replaces the value of key to new value if it
(K key, V oldValue, V newValue)	contains old value.

HashMap Class

- ☐ This class implements **Map** interface.
- ☐ It does not guarantee the order of keys.

HashMap() HashMap(Map)

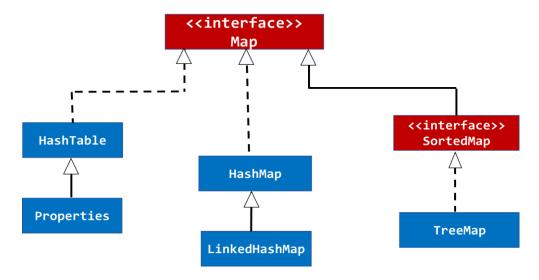

NOTE: HashTable class is same as HashMap class, but it is synchronized. LinkedHashMap class extends HashMap class and arranges keys in the order of insertion.

SortedMap Interface

This interface extends **Map** interface to provide sorted keys.

The following are the methods that are added in **SortedMap** interface compared with **Map** interface.

Method	Meaning
Object first()	Returns the first element.
Object last()	Returns the last element.
SortedSet headMap	Returns list up to the specified element and not
(Object toKey)	including it.
SortedSet tailMap	Returns list from the specified element up to end
(Object fromKey)	of the list.
SortedSet subMap(object	Returns list that contains elements from the given
fromKey, object toKey)	fromKey to toKey but not including it.

TreeMap Class

- ☐ This class implements **SortedMap** interface. It arranges keys in the sorted order.
- Order of keys is either natural order or specified by **Comparator.**

TreeMap() TreeMap(Comparator)

The following program uses HashMap, LinkedHashMap and TreeMap to show the way these classes arrange keys.

```
01: import java.util.HashMap;
02: import java.util.LinkedHashMap;
03: import java.util.TreeMap;
04:
05: public class MapDemo {
      public static void main(String[] args) {
06:
            HashMap<String, String> hm = new HashMap<>();
07:
            hm.put("java", "Language");
08:
            hm.put("dotnet", "Framework");
09:
            hm.put("c#", "Language");
10:
11:
            System.out.println("HashMap Output");
            for (String key : hm.keySet())
12:
               System.out.printf("%s:%s\n",key,hm.get(key));
13:
14:
15:
            // Arranges keys in insertion order
            LinkedHashMap<String,String> lhm
16:
                            = new LinkedHashMap<>();
17:
            lhm.put("java", "Language");
18:
            lhm.put("dotnet", "Framework");
19:
            lhm.put("c#", "Language");
20:
            System.out.println("LinkedHashMap Output");
21:
            for (String key : lhm.keySet())
22:
              System.out.printf("%s:%s\n",key,lhm.get(key));
23:
24:
            // Arranges keys in ascending order
25:
            TreeMap<String, String> tm = new TreeMap<>();
26:
27:
            tm.put("java", "Language");
            tm.put("dotnet", "Framework");
28:
            tm.put("c#", "Language");
29:
            System.out.println("TreeMap Output");
30:
            for (String key : tm.keySet())
31:
              System.out.printf("%s:%s\n",key,tm.get(key));
32:
33:
      }
34:
```

Properties Class

ш	Represents a persistent set of properties.
	Properties can be saved to a stream or loaded from a stream.

- Each key and its corresponding value in the property list is a string.
- ☐ Properties class extends **HashTable** class.

Method	Meaning
String getProperty	Searches for the property with the specified key in this
(String key)	property list.
void list	Prints this property list out to the specified output
(PrintWriter out)	stream.
void load	Reads a property list (key and element pairs) from the
(Reader reader)	input character stream in a simple line-oriented
	format.
Object setProperty	Adds a new property.
(String key, String value)	
void store	Writes this property list (key and element pairs) in
(Writer writer,	this Properties table to the output character stream in
String comments)	a format suitable for using the load method.

```
import java.util.Properties;
01:
   import java.io.*;
02:
03: public class PropertyDemo {
     public static void main(String[]args) throws Exception{
04:
       Properties p = new Properties();
05:
       p.setProperty("name", "Srikanth");
06:
       p.setProperty("email","srikanth@gmail.com");
07:
       p.setProperty("phone","9059057000");
08:
       for(Object k : p.kevSet())
09:
         System.out.printf("%s : %s\n", k, p.get(k));
10:
11:
       p.store(new FileWriter("c:\\java\\sri.properties"),
12:
13:
                                "Srikanth Details");
       Properties p2= new Properties();
14:
       p2.load(new FileReader("c:\\java\\sri.properties"));
15:
       for(Object k : p2.keySet())
16:
         System.out.printf("%s : %s\n", k, p2.get(k));
17:
     }
18:
19:}
```

Collections Class

☐ It contains a collection of static methods that operate on collections provided as parameters of the collection.

☐ Implements various algorithms related to collections.

Method	Meaning
int binarySearch(List I, Object v)	Implements binary search algorithm to search.
void copy(List dest, List src)	Copies content of one list to another.
void fill(List list, Object obj)	Fills the list with the given value.
Object max (Collection c)	Returns maximum value in collection.
Object min (Collection c)	Returns minimum value in collection.
void reverse(List I)	Reverses the list.
void shuffle(List I)	Shuffles the list with default randomness.
void sort(List I)	Sorts the list.
void sort(List I, Comparator c)	Sorts the list with order specified by
	Comparator.

```
import java.util.*;
01:
02: public class CollectionsDemo {
     public static void main(String args[]) {
03:
      ArrayList<String> names = new ArrayList<> ();
04:
      names.add("James Goodwill");
05:
      names.add("Jason Hunter");
06:
07:
      names.add("Roman");
      Collections.sort(names);
08:
      printList(names);
09:
     int pos = Collections.binarySearch(names, "Roman");
10:
11:
      System.out.printf("Roman is found at: %d\n", pos);
      System.out.printf("Max:%s\n", Collections.max(names));
12:
13:
      System.out.println("Reverse Order");
14:
      Collections.reverse(names);
15:
      printList(names);
16:
17:
     public static void printList(List<String> list) {
18:
19:
     for (String s: list) {
        System.out.println(s);
20:
21:
      }
22:
     }
23: }
```

253

Immutable Collections

- ☐ Collection is immutable i.e., we can't add, delete or modify elements.
- Nulls are not allowed.
- ☐ Serializable if all elements are serializable.
- ☐ We can create a list of up to 10 elements as there are 10 parameters for of() method.
- ☐ List.<E>of (E...elements) can take any number of parameters including an array.

The following are methods to create immutable collections:

```
List.of()
List.of(values)
Set.of()
Set.of(values)
Map.of()
Map.of(key, value, key, value,...)
Map.ofEntries(Map.Entry ... entries)
```

```
// Immutable Empty List
List<String> emptyList = List.of();

// Immutable List
List<String> immutableList= List.of("one","two","three");
```

```
// Immutable Empty Map
Map
Map
Map
Map
Map
Map using Map.of()

Map
Map
String> phones =
Map.of("Bill","39393393988","Larry","9988776655");

// Immutable Map using Map.ofEntries()
Map<Integer,String> map =
Map.ofEntries(Map.entry(1,"One"),Map.entry(2,"Two"));
```

Generic Methods

- ☐ All generic method declarations have a type parameter section delimited by angle brackets (< and >) that precedes the method's return type (<T> in this example).
- □ Note that type parameters can represent only reference types—not primitive types (like int, double and char).
- ☐ Type parameter can be declared only once in the type parameter section but can appear more than once in the method's parameter list.

Bounded Type Parameter

- To declare a bounded type parameter, list the type parameter's name, followed by **extends** keyword, followed by upper bound.
- Note that, in this context, **extends** is used in a general sense to mean either "extends" (as in classes) or "implements" (as in interfaces).

```
01: import java.util.*;
02: public class GenericMethods {
03:
       public static <T> void print(T a[]) {
04:
          for(T v : a)
            System.out.println(v);
05:
06:
       public static<T extends Comparable<T>>
07:
08:
        boolean contains(T a[], T v) {
          for (T value: a)
09:
                   if(value.compareTo(v) == 0)
10:
11:
                 return true;
12:
          return false;
13:
       public static void main(String args[]) {
14:
          String names[]={"Steve","Joe","Bob","James"};
15:
          print(names);
16:
          System.out.println(contains(names, "Joe"));
17:
       }
18:
19: }
```

Regular Expressions

- ☐ Regular expressions are a way to describe a set of strings based on common characteristics shared by each string in the set.
- ☐ They can be used to search, edit, or manipulate text and data.
- ☐ You must learn a specific syntax to create regular expressions one that goes beyond the normal syntax of the Java programming language.

Character Classes

The following are the available character classes.

The left-hand column specifies the regular expression constructs, while the right-hand column describes the conditions under which each construct will match.

[abc]	a, b, or c (simple class)	
[^abc]	Any character except a, b, or c (negation)	
[a-zA-Z]	a through z, or A through Z, inclusive (range)	
[a-z&&[^bc]]	a through z, except for b and c: [ad-z] (subtraction)	
[a-z&&[^m-p]]	a through z, and not m through p: [a-lq-z] (subtraction)	

Predefined character classes

The following are the predefined character classes.

	Any character (may or may not match line terminators)	
\d	A digit: [0-9]	
\D	A non-digit: [^0-9]	
\s	A whitespace character: [\t\n\x0B\f\r]	
\S	A non-whitespace character: [^\s]	
\w	A word character: [a-zA-Z_0-9]	
\W	A non-word character: [^\w]	

Quantifiers

The following are the available quantifiers.

X?	X, once or not at all	
X*	X, zero or more times	
X+	X, one or more times	
X{n}	X, exactly n times	
X{n,}	X{n,} X, at least n times	
X{n,m}	X, at least n but not more than m times	

Pattern Class

	A Pattern ob	iect is a com	niled represe	ntation of a r	egular expr	ession.
_	/ \	icct is a con	ipiica i cpi csc	illudion of a i	Chain Cybi	CJJIOII.

- ☐ The Pattern class provides no public constructors.
- ☐ To create a pattern, you must first invoke one of its public static compile methods, which will then return a Pattern object.
- ☐ These methods accept a regular expression as the first argument.

Method	Meaning
static Pattern	Compiles the given regular expression into a pattern.
compile(String regex)	
Matcher matcher	Creates a matcher that will match the given input
(CharSequence input)	against this pattern.
static boolean	Compiles the given regular expression and attempts to
matches(String regex,	match the given input against it.
CharSequence input)	
String pattern()	Returns the regular expression from which this pattern
	was compiled.
String[] split	Splits the given input sequence around matches of this
(CharSequence input)	pattern.

```
01: import java.util.Scanner;
   import java.util.regex.Pattern;
02:
03: public class MobileNumber {
       public static void main(String[] args) {
04:
         Scanner s = new Scanner(System.in);
05:
         System.out.print("Enter mobile number : ");
06:
07:
         String mobile = s.nextLine();
         // other way is: mobile.matches("^\\d{10}$")
08:
         if (Pattern.matches("^\\d{10}$", mobile))
09:
           System.out.println("Valid mobile number!");
10:
11:
         else
12:
           System.out.println("Invalid mobile number!");
13:
       }
14: }
```

```
01: import java.util.regex.Pattern;
02: public class SplitDemo {
03:  public static void main(String[] args) {
04:    Pattern p = Pattern.compile("\\d");
05:    String[] items=p.split("one9two4three7four1five");
06:    for(String s : items)
07:        System.out.println(s);
08:    }
09: }
```

Matcher Class

- A Matcher object is the engine that interprets the pattern and performs match operations against an input string.
- ☐ Like the Pattern class, Matcher defines no public constructors.
- ☐ You obtain a Matcher object by invoking the matcher method on a Pattern object.

Method	Meaning
int end()	Returns the index of the last character matched, plus one.
boolean find()	Attempts to find the next subsequence of the input sequence
	that matches the pattern.
String group()	Returns the input subsequence matched by the previous
	match.
boolean matches()	Attempts to match the entire input sequence against pattern.
Pattern pattern()	Returns the pattern that is interpreted by this matcher.
String replaceAll	Replaces every subsequence of the input sequence that
(String replacement)	matches the pattern with the given replacement string.
String replaceFirst	Replaces the first subsequence of the input sequence that
(String replacement)	matches the pattern with the given replacement string.
int start()	Returns the start index of the previous match.

```
01: import java.util.regex.*;
02: public class MatcherDemo {
     public static void main(String[] args) {
03:
04:
       Pattern p = Pattern.compile("[a-z]+");
       Matcher m = p.matcher("123bbc4343pgr3433");
05:
06:
       while(m.find()) {
          System.out.println("start(): " + m.start());
07:
          System.out.println("end(): "+ m.end());
08:
          System.out.println("group(): " + m.group());
09:
       }
10:
11:
       // pattern replacement
       p = Pattern.compile("-+");
12:
       m = p.matcher("----12345----");
13:
       String output = m.replaceAll("*");
14:
       System.out.println(output):
15:
16:
    }
17: }
```

```
start(): 3
end(): 6
group(): bbc
start(): 10
end(): 13
group(): pqr
*12345*
```

Lambda Expressions

- ☐ Lambda expression allows functionality to be passed as argument to a method.
- ☐ It is a replacement for Anonymous class that implements single abstract method (SAM) interface functional interface.

Components of Lambda Expression

- ☐ A comma-separated list of formal parameters enclosed in parentheses.
- ☐ You can omit parentheses if there is only one parameter.
- ☐ The arrow token -> also known as *lambda operator*.
- ☐ A body, which consists of a single expression or a statement block.
- ☐ If you specify a single expression, then the Java runtime evaluates the expression and then returns its value. No return statement is required.
- ☐ Statement block must be enclosed in statements in braces ({}), and must have a return statement.

(parameters) -> expression

```
(int n1, int n2) -> n1 > n2
(n1, n2) -> n1 > n2
```

Variable Scoping

- ☐ Lambdas are lexically scoped. They do not introduce a new level of scoping.
- ☐ The **this** variable refers to the outer class, not to the anonymous inner class that the lambda is turned into.
- ☐ There is no need for **OuterClass.this** variable unless lambda is inside a normal inner class.
- ☐ Lambdas cannot introduce new variables with same name as variables in method that creates the lambda.
- ☐ However, lambdas can refer to (but not modify) local variables from the surrounding code.
- ☐ Lambdas can still refer to (and modify) instance variables from the surrounding class.

```
01: interface Test {
        boolean eval(int n1, int n2);
02:
03: }
04: public class LambdaDemo1 {
        public static void main(String[] args) {
05:
96:
         // Old Anonymous inner class demo
         Test t = new Test() {
07:
08:
              @Override
              public boolean eval(int n1, int n2) {
09:
10:
                  return n1 > n2;
11:
              }
12:
         };
13:
         System.out.println(t.eval(20,10));
14:
15:
         // Lambda expression
         Test t2 = (int n1, int n2) \rightarrow n1 > n2;
16:
         System.out.println(t2.eval(20,10));
17:
18:
         // type inference, no need to mention data types
19:
20:
         Test t3 = (n1, n2) \rightarrow n1 > n2;
         System.out.println(t3.eval(20,10));
21:
22:
       }
23: }
```

Method Reference

- ☐ We use lambda expressions to create anonymous methods. However, when a lambda expression does nothing but call an existing method, we can use method reference.
- ☐ Method references are compact, easy-to-read lambda expressions for methods that already have a name.

The following example shows how to use method reference to create a new thread.

```
public class ThreadWithLambda {
01:
02:
      public static void main(String[] args){
03:
        // New thread with lambda expression
        Thread t1 = new Thread(() -> {
04:
05:
           for(int i=1; i <= 10; i++)
                  System.out.println(i);
06:
07:
        });
        t1.start();
08:
99:
        // Method reference
10:
        Thread t2 = new Thread(ThreadWithLambda::print);
11:
12:
        t2.start();
13:
14:
      static public void print() {
        for (int i = 1; i <= 10; i++) {
15:
          System.out.println(i);
16:
17:
      }
18:
19: }
```

Kinds of Method References

The following are four kinds of method references.

Reference to a static method	ContainingClass::staticMethodName
Reference to an instance	ContainingObject::instanceMethodName
method of a particular object	
Reference to an instance	ContainingType::methodName
method of an arbitrary object of	
a particular type	
Reference to a constructor	ClassName::new

```
01: public class MyTime {
       private int hours, mins, secs;
02:
       public MyTime(int hours, int mins, int secs) {
03:
04:
          this.hours = hours;
          this.mins = mins;
05:
06:
          this.secs = secs;
07:
08:
       @Override
       public String toString() {
09:
          return "MyTime{" + "hours=" + hours + ",
10:
11:
                    mins=" + mins + ", secs=" + secs + '}';
12:
13:
       public int totalSeconds() {
          return hours * 3600 + mins * 60 + secs;
14:
15:
       public static int compare(MyTime t1, MyTime t2) {
16:
          return t1.totalSeconds() - t2.totalSeconds();
17:
18:
       }
19: }
```

```
01: import java.util.*;
02: public class SortWithLambda {
      public static void main(String[] args) {
03:
04:
        ArrayList<MyTime> times = new ArrayList();
05:
        times.add(new MyTime(10,10,20));
06:
        times.add(new MyTime(5,30,20));
        times.add(new MyTime(20,5,10));
07:
        Collections.sort(times,
08:
           (t1,t2)-> t1.totalSeconds()-t2.totalSeconds());
09:
        for(MyTime t : times)
10:
11:
           System.out.println(t.toString());
12:
        // Method reference
13:
        Collections.sort(times, MyTime::compare);
        for(MyTime t : times)
14:
           System.out.println(t.toString());
15:
      }
16:
17: }
```

Built-in Functional Interfaces

	New ones are added in java.util.function package.
	Comparator or Runnable.
	Some of them are well known from older versions of Java like Comparable ,
_	The Java & AFT contains many built-in functional interfaces.

- ☐ Many of these functional interfaces have default methods other than functional (abstract) method.

Interface	Description
Consumer <t></t>	Represents an operation that accepts a single input argument and returns no result. Functional method is accept(T).
Function <t,r></t,r>	Represents a function that accepts one argument and produces a result. Functional method is apply (T) and returns R.
Predicate <t></t>	Represents a predicate (boolean-valued function) of one argument. Functional method is test (T) and returns Boolean.
Supplier <t></t>	Represents a supplier of results. Functional method is get () that returns T.
UnaryOperator <t></t>	Applies a unary operation to an object of type T and returns T. The method is apply (T).
BinaryOperator <t></t>	Applies an operation to two objects of type T and returns the result of type T. Method is apply (T, T).

```
import java.util.function.*;
01:
02:
   public class BuiltInFunctionalInterfaces {
     public static void main(String[] args) {
03:
04:
       Consumer<String> c=(s) ->
             System.out.println(s.toUpperCase());
05:
       c.accept("Srikanth");
06:
       Predicate<String> p = (s) -> s.length() > 5;
07:
       System.out.println(p.test("Java"));
08:
09:
       Function<Integer,String> f=(n)->n.toString();
       System.out.println(f.apply(100));
10:
11:
    }
12: }
```

Streams

A stream is a sequence of elements supporting sequential and parallel
aggregate operations. Unlike a collection, stream is not a data structure that stores elements. Instead a stream carries values from a source through a pipeline of operations.
Stream operations are either <i>intermediate</i> or <i>terminal</i> .
Source of stream could be a collection, an array, a generator function, or an I/C channel.
An intermediate operation, such as filter, produces a new stream.
A terminal operation, such as $\ensuremath{\text{forEach}}, \ensuremath{\text{produces}}$ a non-stream result, such as a
primitive value (like a double value), a collection, or in the case of forEach, no value at all. They are also called as <i>reduction operations</i> .
Starting from Java 8, the java collections have methods that return Stream.
Streams support Aggregate Operations and common aggregate operations are
filter, map, reduce, find, match, and sort. These operations can be executed in
series or in parallel.

Method	Description	
boolean allMatch	Returns whether all elements of this	
(Predicate super T predicate)	stream match the provided predicate.	
boolean anyMatch	Returns whether any element of this	
(Predicate super T predicate)	stream matches the provided predicate.	
long count()	Returns the count of elements in this	
	stream.	
Stream <t> distinct()</t>	Returns a stream consisting of the distinct	
	elements (according	
	to Object.equals(Object)) of this stream.	
static <t>Stream<t> empty()</t></t>	Returns an empty sequential Stream.	
Stream <t>filter</t>	Returns a stream consisting of the	
(Predicate super T predicate)	elements of this stream that match the	
	given predicate.	

Optional <t>findAny()</t>	Returns an Optional describing some
	element of the stream, or an
	empty Optional if the stream is empty.
Optional <t>findFirst()</t>	Returns an Optional describing the first
	element of this stream, or an
	empty Optional if the stream is empty.
void forEach	Performs an action for each element of this
(Consumer super T action)	stream.
void forEachOrdered	Performs an action for each element of this
(Consumer super T action)	stream, in the encounter order of the
	stream if the stream has a defined
	encounter order.
Stream <t> limit(long maxSize)</t>	Returns a stream consisting of the
	elements of this stream, truncated to be
	no longer than maxSize in length.
Stream map	Returns a stream consisting of the results
(Function super T,</td <td>of applying the given function to the</td>	of applying the given function to the
? extends R> mapper)	elements of this stream.
Optional <t>max</t>	Returns the maximum element of this
(Comparator super T comp)	stream according to the
	provided Comparator.
Optional <t>min</t>	Returns the minimum element of this
(Comparator super T comp)	stream according to the
	provided Comparator.
boolean noneMatch	Returns whether no element of this stream
(Predicate super T predicate)	matches the provided predicate.
Stream <t>skip(long n)</t>	Returns a stream consisting of the
	remaining elements of this stream after
	discarding the first n elements of the
	stream.

Stream <t>sorted()</t>	Returns a stream consisting of the elements of this stream, sorted according to natural order.
Stream <t>sorted (Comparator<? super T> comp)</t>	Returns a stream consisting of the elements of this stream, sorted according to the provided Comparator.
Object[] toArray()	Returns an array containing the elements of this stream.
Stream <t> iterate (T seed, Predicate<? super T> hasNext, UnaryOperator<t> next)</t></t>	Returns a sequential ordered Stream produced by iterative application of the given next function to an initial element, conditioned on satisfying the given hasNext predicate.
Stream <t> takeWhile (Predicate<? super T> predicate)</t>	Returns a stream with all the values from the beginning of the stream as long as condition is true.
Stream <t> dropWhile (Predicate<? super T> predicate)</t>	Returns a stream with values from first value where condition is false.

forEach() Limitations

- ☐ Cannot loop twice as it consumes the elements of the stream.
- ☐ Cannot break out of the loop.
- ☐ Can't change surrounding local variables.

Stream.of() Method

It is possible to build a stream by providing values to **of**() method in Stream interface.

```
// Build a stream
Stream.of(10,21,22,35,55,30)
   .filter(n -> n % 2==0).forEach(System.out::println);
```

270

Java SE Course Material

Streams from Arrays

An array can be source of stream. Arrays.stream() method can be used to build a stream from an array.

```
String [] names = {"Joe", "Andy", "Steve", "Bob", "Jason"};
Arrays.stream(names)
   .filter(n -> n.length() > 3).forEach(System.out::println);
```

```
01: import java.util.*;
02: import java.util.stream.Stream;
03: public class StreamsDemo {
     public static void main(String[] args) {
04:
      ArrayList<MyTime> times=new ArrayList<MyTime>();
05:
06:
     times.add(new MyTime(20,45,55));
     times.add(new MyTime(10,34,30));
07:
      times.add(new MyTime(14,15,20));
08:
     times.add(new MyTime(7,10,50));
09:
     times.stream()
10:
          .filter(t -> t.getHours() > 10).limit(2)
11:
          .forEach(System.out::println);
12:
13:
      // Convert object to int
      double average=times.stream()
14:
15:
          .mapToInt(MyTime::totalSeconds)
          .average().getAsDouble();
16:
      System.out.println(average);
17:
      System.out.println("Any Hours > 12 ? " +
18:
          times.stream().anyMatch(t->t.getHours()>12));
19:
20:
      System.out.println("All Hours > 12 ? " +
          times.stream().allMatch(t->t.getHours()>12));
21:
      System.out.println("Count = " +
22:
          times.stream().count());
23:
      Optional<MyTime> mintime=times.stream()
24:
         .min((t1,t2)->t1.totalSeconds()-t2.totalSeconds());
25:
      System.out.println("Minimum = " + mintime.get());
26:
27:
28:
```

Streams from IO

The following example shows how to create a stream from lines of a file and sort the stream before printing lines.

```
var lines =
Files.lines(Paths.get("c:\\classroom\\names.txt"));
lines.sorted().forEach(System.out::println);
lines.close();
```

Using takeWhile(), dropWhile() and iterate()

The following snippets show how to use takeWhile(), dropWhile() and iterate()

Parallelism in Streams

- ☐ Parallel computing involves dividing a problem into subproblems, solving those problems simultaneously (in parallel, with each subproblem running in a separate thread), and then combining the results of the solutions to the subproblems.
- ☐ It is possible to obtain a parallel stream from a source that provides a stream using method **parallelStream()**.
- ☐ When a stream executes in parallel, the Java runtime partitions the stream into multiple substreams. Aggregate operations iterate over and process these substreams in parallel and then combine the results.

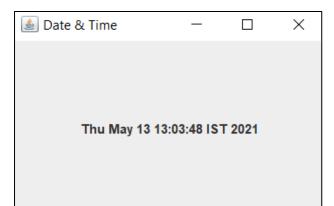

Desktop Applications Using Swing

Swing Library

- ☐ Swing components are built as part of **JFC** (Java Foundation Classes).
- ☐ Swing components are light weight components as they are written in Java.
- ☐ Swing components are built on the top of AWT.
- ☐ Swing components are consistent across all platforms they look and work alike on all platforms.
- ☐ It is also possible to change the look and feel of a swing application at runtime using *Pluggable look and feel (PL&F)* features of swing.
- ☐ Swing components are made available in **javax.swing** package.

Developing Swing Application

- Unlike an Applet, a frame-based application displays a frame and doesn't need any container to run it.
- ☐ A swing application contains **main()** method, where the application starts.
- ☐ It extends **JFrame** class.

```
01: import javax.swing.*;
02: import java.awt.*;
03: import java.util.Date;
04:
05: public class SimpleFrame extends JFrame {
06:
      public SimpleFrame() {
        super("Date & Time"); // title
07:
        Container c = getContentPane();
08:
        JLabel lbl = new JLabel():
09:
        // center message horizontally
10:
11:
        lbl.setHorizontalAlignment(JLabel.CENTER);
        lbl.setText (new Date().toString());
12:
13:
        c.add (lbl);
        this.setDefaultCloseOperation(JFrame.EXIT ON CLOSE);
14:
15:
16:
        public static void main(String args[]) {
17:
          SimpleFrame f = new SimpleFrame();
18:
          f.setSize(300,200);
19:
20:
          f.setVisible(true);
21:
22: }
```

NOTE: Method **setDefaultCloseOperation**() specifies the action to be taken when user clicks on close button of the frame.

Container Class

A container is a component that can contain other components. Classes like **Panel** and **Window** extend Container class. The following are the important methods of **Container** class.

Method	Meaning
Component add(Component c)	Adds the component to the container
	(typically at the end).
Component add	Adds the component at the given
(Component c, int pos)	position.
void add(Component c,	Adds the component with the given
Object constraints)	constraints.
Component getComponentAt (Point p)	Returns the component that is at the
	specified point.
Component[] getComponents()	Returns all components of the
	container.
LayoutManager getLayout()	Returns current layout manager.
void setLayout(LayoutManager)	Changes layout manager.

JComponent Class

A **component** is an object having a graphical representation that can be displayed on the screen and that can interact with the user. Examples of components are buttons, checkboxes, and scrollbars of a typical graphical user interface.

AWT components are created from **Component** class. Swing components are created from **JComponent** class, whose hierarchy is shown below.

```
java.lang.Object
|--java.awt.Component
|--java.awt.Container
|-- javax.swing.JComponent
```

The following are the important methods of **JComponent** class in different categories.

Component Appearance

Methods related to appearance of the Component.

Method	Meaning
void setBorder(Border)	Set or get the border of the component.
Border getBorder()	
void setForeground(Color)	Set the foreground or background color for the
void setBackground(Color)	component.
Color getForeground()	Get the foreground or background color for the
Color getBackground()	component.
void setOpaque(boolean)	Set or get whether the component is opaque. An
boolean isOpaque()	opaque component fills its background with its
	background color.
void setFont(Font)	Set or get the component's font. If a font has not
Font getFont()	been set for the component, the font of its parent
	is returned.

Setting and Getting Component State

Methods related to Component state.

Method	Purpose
<pre>void setToolTipText(String)</pre>	Sets the text to display in a tool tip.
void setEnabled(boolean)	Set or get whether the component is enabled. An
boolean isEnabled()	enabled component can respond to user input and
	generate events.
void setVisible(boolean)	Set or get whether the component is visible.
boolean isVisible()	Components are initially visible, with the exception
	of top-level components such as JFrame and
	JDialog.

Laying Out Components

Methods related to layout of the Component.

Method	Purpose
void setPreferredSize(Dimension) void setMaximumSize(Dimension) void setMinimumSize(Dimension)	Set the component's preferred, maximum, or minimum size, measured in pixels. The preferred size indicates the best size for the component. The component should be no larger than its maximum size and no smaller than its minimum size. Be aware that these are hints only and might be ignored by certain layout managers.
Dimension getPreferredSize()	Get the preferred, maximum, or minimum
Dimension getMaximumSize() Dimension getMinimumSize()	size of the component, measured in pixels.
int getWidth() int getHeight()	Get the current width or height of the component measured in pixels.
Insets getInsets()	Gets the size of the component's border.
void setBounds(int, int, int, int) void setBounds (Rectangle)	Set the size of the component's border. Set the size and location relative to the parent's upper left corner, in pixels, of the component. Use these methods to position and size a component when you aren't using a layout manager.

Layout Managers

	Layout Manager is used to arrange components using an algorithm.
	Each container has an associated layout manager which arranges the
	components added to container.
	It determines the size and position of the components within a container.
	Although components can provide size and alignment hints, a container's
	layout manager has the final say on the size and position of the components
	within the container.
	Layout manager manages all the differences between platforms there by
	shielding programs from nitty-gritty of different platforms.
\Box	Method set avout() is used to change the layout manager of a container

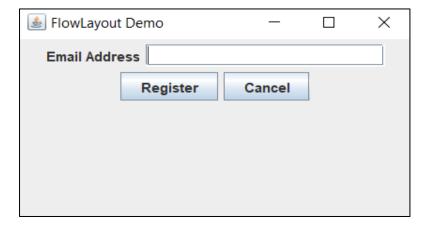

Layout Manager	Description				
FlowLayout	Components are arranged from upper-left corner, left to right and top to bottom. If a row is not sufficient to place				
	components, then it starts a new row.				
GridLayout	Lays out components in two-dimensional grid. Each cell in the grid will be of the same size. Each component takes all				
	the space available in cell.				
GridBagLayout	Divides the area into cells where width and height and other attributes of each component can be specified in terms of cells.				
BorderLayout	The entire area is divided into 5 areas—PAGE_START, PAGE_END, LINE_START, LINE_END and CENTER. We have to specify the area in which the component is to be placed. Default is CENTER.				
CardLayout	Allows a set of cards to be placed in such a way that only one card can be displayed at a time.				
BoxLayout	This layout manager places components either vertically or horizontally.				
GroupLayout	Allows horizontal and vertical dimensions to be handled separately.				

Using FlowLayout

- ☐ This layout puts components in a row, sized at their preferred size.
- ☐ If the horizontal space in the container is too small to put all the components in one row, it uses multiple rows.
- If the container is wider than necessary for a row of components, the row is, by default, centered horizontally within the container.

```
FlowLayout()
FlowLayout(int alignment)
FlowLayout(int alignment, int horzGap, int vertGap)
```

The alignment can be *FlowLayout.LEADING*, *FlowLayout.CENTER*, or *FlowLayout.TRAILING*. Default gap value is 5 units.

```
01: import javax.swing.*;
02: import java.awt.*;
03: public class FlowLayoutDemo extends JFrame {
        JLabel 11; JTextField tfEmail;
04:
05:
        JButton b1, b2;
06:
        public FlowLayoutDemo() {
          super("FlowLayout Demo");
07:
          11 = new JLabel("Email Address");
08:
          tfEmail = new JTextField(20);
09:
          b1= new JButton("Register");
10:
          b2 = new JButton("Cancel");
11:
          Container c = getContentPane();
12:
13:
          c.setLayout(new FlowLayout());
14:
          c.add(11);
15:
          c.add(tfEmail);
16:
          c.add(b1);
17:
          c.add(b2);
          setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
18:
          setSize(350,200);
19:
20:
          setVisible(true);
21:
22:
        public static void main(String args[]) {
          new FlowLayoutDemo();
23:
24:
        }
25: }
```

Using GridLayout

GridLayout places components in grid cells. The total area is divided into rows and columns specified by constructor of GridLayout. All cells are of exactly same size.

```
GridLayout(int rows, int columns)
GridLayout(int rows, int columns,int horizGap, int vertGap)
```

If rows is zero then as many rows as required are created. If columns is zero then as many columns as required are created.

NOTE: At least rows parameter or columns parameter must be non-zero.

The following program places three buttons in one row. It creates as many rows as required to accommodate buttons.

```
01: import java.awt.Container;
02: import java.awt.GridLayout;
03: import javax.swing.JButton;
04: import javax.swing.JFrame;
05:
06: public class GridLayoutDemo extends JFrame {
      public GridLayoutDemo() {
07:
         super("GridLayout Demo");
08:
         Container c = getContentPane();
09:
10:
         c.setLayout(new GridLayout(0, 3));
         for (int i = 1; i <= 8; i++)
11:
            c.add(new JButton("Button" + i));
12:
         setDefaultCloseOperation(JFrame.EXIT ON CLOSE);
13:
         setSize(350, 200);
14:
         setVisible(true);
15:
16:
17:
      public static void main(String args[]) {
         new GridLayoutDemo();
18:
19:
      }
20: }
```

		_		×
Button1	Button2	Button3		
Button4	Button5		Button6	
Button7	Button8			

Using BorderLayout

- ☐ It divides the space into five areas. Each area takes one component.
- Except center area, other areas take only as much space as required. The rest of the space is given to center area.
- ☐ LINE_START and LINE_END areas grow vertically to occupy the vacant area.
- ☐ PAGE_START and PAGE_END areas grow horizontally to occupy the vacant area.
- ☐ By default, BorderLayout puts no gap between the components.

BorderLayout() BorderLayout(int horizGap, int vertGap)

These areas are identified by the following constants:

- ✓ BorderLayout.PAGE_START
- ✓ BorderLayout.PAGE END
- ✓ BorderLayout.LINE START
- ✓ BorderLayout.LINE END
- ✓ BorderLayout.CENTER

NOTE: These areas can also be referred as NORTH, SOUTH, WEST, EAST and CENTER. The default area is CENTER.

The following example shows how to place components in BorderLayout.

```
01: import javax.swing.*;
02: import java.awt.*;
03: public class BorderLayoutDemo extends javax.swing.JFrame {
   public BorderLayoutDemo() {
04:
05:
      super("BorderLayout Demo");
06:
      Container c = getContentPane();
07:
      c.add(new JButton("Top Button"),BorderLayout.PAGE START);
      c.add(new JButton("Bottom Button"),BorderLayout.PAGE END);
08:
      c.add(new JButton("Left Button"),BorderLayout.LINE_START);
09:
      c.add(new JButton("Right Button"), BorderLayout.LINE END);
10:
11:
      // place multiple components at the center using JPanel
12:
      JPanel p = new JPanel(); // default FlowLayout
13:
      p.add(new JLabel("Label"));
14:
      p.add(new JTextField(20));
15:
      c.add(p); // placed at center
      setDefaultCloseOperation(JFrame.EXIT ON CLOSE);
16:
17:
      setSize(500,200);
18:
      setVisible(true);
19: }
20:
21: public static void main(String args[]) {
22:
      new BorderLayoutDemo();
23: }
```

Using GridBagLayout

GridBagLayout is very flexible but complex layout manager. It allows components to be placed at the specified position in terms of cells. A component may span multiple rows and columns.

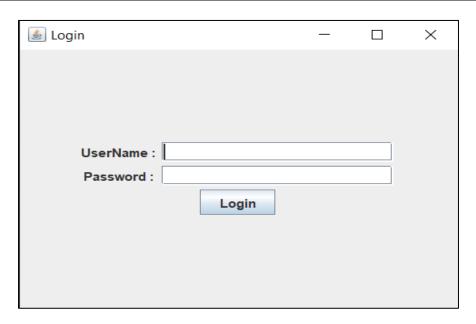

Unlike GridLayout, all components need not be of the same size.

GridBagConstraints is used to specify the properties (position and size) related to each component.

GridBagLayout()

```
01: import java.awt.*;
02: import javax.swing.*;
03:
04: public class UserLoginFrame extends JFrame {
      JTextField tfUname;
05:
06:
      JPasswordField tfPwd;
07:
      JButton btnLogin;
      public UserLoginFrame() {
08:
09:
        super("Login");
        GridBagConstraints gbc = new GridBagConstraints();
10:
        tfUname = new JTextField(20);
11:
12:
        tfPwd = new JPasswordField(20);
13:
        btnLogin = new JButton("Login");
        Container c = getContentPane();
14:
        c.setLayout(new GridBagLayout());
15:
        setDefaultCloseOperation
16:
                    (WindowConstants.EXIT ON CLOSE);
17:
        // first label
18:
        c.add(new JLabel("UserName : "), gbc);
19:
```

```
20:
           // username
21:
           gbc.gridwidth = 2;
22:
           gbc.fill = GridBagConstraints.HORIZONTAL;
23:
           gbc.insets = new java.awt.Insets(2, 2, 2, 2);
           c.add(tfUname, gbc);
24:
25:
            // second label
26:
            gbc.gridx = 0;
27:
28:
            gbc.gridy = 1;
            c.add(new JLabel("Password : "), gbc);
29:
30:
31:
            // password
            gbc.gridx = 1;
32:
33:
            gbc.gridwidth = 2;
            gbc.insets = new java.awt.Insets(2, 2, 2, 2);
34:
            c.add(tfPwd, gbc);
35:
36:
37:
            // button
38:
            gbc.gridx = 0;
39:
            gbc.gridy = 2;
            gbc.gridwidth = 3;
40:
            gbc.fill = GridBagConstraints.NONE;
41:
42:
            gbc.insets = new java.awt.Insets(2, 2, 2, 2);
            c.add(btnLogin, gbc);
43:
44:
      }
45:
46:
      public static void main(String args[]) {
            UserLoginFrame f = new UserLoginFrame();
47:
            f.setSize(400, 300);
48:
            f.setVisible(true);
49:
      }
50:
51: }
```

290

Properties of GridBagConstraints

Properties of **GridBagConstraints** are used to specify how to position and size a component in GridBagLayout. Each component that is placed in GridBagLayout must be associated with properties specified by GridBagConstraints object.

The following table lists properties and their meaning.

Property	Meaning
gridx, gridy	Specify the column and row positions. The upper left is 0, 0.
gridwidth,	Specify the number of columns and rows in the component's
gridheight	display area. The default value is 1.
fill	Used when the component's display area is larger than the
	component's requested size to determine whether and how to
	resize the component. Valid values are NONE (the default), HORIZONTAL, VERTICAL and BOTH.
anchor	Used when the component is smaller than its display area to
	determine where (within the area) to place the component.
	Valid values (defined as GridBagConstraints constants) are :
	CENTER (the default), PAGE_START, PAGE_END, LINE_START,
	LINE_END, FIRST_LINE_START, FIRST_LINE_END,
	LAST_LINE_END, and LAST_LINE_START.
weightx,	Weights are used to determine how to distribute space among
weighty	columns and among rows.
	Default weight is 0.0. Valid range is 0.0 to 1.0.

Using Absolute positioning - Null Layout Manager

- ☐ It is possible to use no layout manager and position component at absolute location. However, absolute position must be used sparingly.
- ☐ If components size is not depending on the size of the container, then absolute position may make sense.
- ☐ In order to use absolute positioning, set layout manager of the container to **null** and use **setBounds()** method for each component to specify left, right, width and height.

```
01: import javax.swing.*;
02: import java.awt.*;
    public class NullLayoutDemo extends JFrame {
03:
        public NullLayoutDemo() {
04:
          super("NullLayout Demo");
05:
          Container c= getContentPane();
06:
          c.setLayout(null);
07:
          JButton b1 = new JButton("First");
08:
          JButton b2 = new JButton("Second");
09:
          JButton b3 = new JButton("Third");
10:
11:
          b1.setBounds(10,20,100,20);
          c.add(b1);
12:
          b2.setBounds(120,30,100,20);
13:
14:
          c.add(b2);
          b3.setBounds(230,40,100,20);
15:
16:
          c.add(b3);
          setSize(350,150);
17:
18:
        public static void main(String args[]) {
19:
          new NullLayoutDemo().setVisible(true);
20:
        }
21:
22:
```

Event handling using Delegation Event Model An event is generated at a component, which is called as source. An object that is interested in the event, generated by source component, must implement appropriate interface and register itself as the listener of the event with event source (component). ☐ Whenever the event occurs in source component a method in the listener is invoked automatically by Java enabling method to perform required action. There are three ways in which you can handle events: ☐ Implement the appropriate interface with a **top-level class** (non-inner class) and define all methods of the interface. Create a top-level class that extends adaptor class, which implements the required interfaces, and overrides only required methods. Use an inner class (may be anonymous) to either extend adaptor class or implement interfaces. Creating action listener to handle action event The following steps are to be taken to handle action event, which occurs when user selects (clicks) a command button. ☐ The listener must implement **ActionListener** interface. ActionListener interface contains actionPerformed (ActionEvent evt) method, which must be defined by listener. The process to be performed by the listener for the event is placed in this method. ☐ Listener must register itself as the listener for action event of source by using addActionListener (ActionListener) method of the source.

The following program has a frame, which contains a button and a label. When user selects button, system date and time is displayed in the label.

```
01: import javax.swing.*;
02: import java.awt.*;
03: import java.awt.event.*;
04: import java.util.Date;
05:
06: public class ActionEventDemo extends JFrame
07:
               implements ActionListener {
08:
        JButton b1;
09:
        JLabel lbl;
        public ActionEventDemo() {
10:
11:
          super("ActionEvent Demo");
          b1 = new JButton("Click Here");
12:
          b1.addActionListener(this);
13:
14:
15:
          lbl = new JLabel();
          lbl.setHorizontalAlignment(JLabel.CENTER);
16:
17:
          Container c = getContentPane();
          c.add(lbl, BorderLayout.PAGE START);
18:
          c.add(b1, BorderLayout.PAGE END);
19:
20:
          setDefaultCloseOperation
21.
                      (WindowConstants.EXIT ON CLOSE);
          setSize(300,200);
22:
23:
       }
24:
       public void actionPerformed(ActionEvent evt) {
25:
26:
          lbl.setText(new Date().toString());
       }
27:
28:
29:
       public static void main(String args[]) {
          new ActionEventDemo().setVisible(true);
30:
31:
       }
32:
```

Handling events with Inner Class

It is possible to handle events by creating an inner class that implements required interface (listener). Inner class can access variables of outer class directly, making it possible for methods of inner class to access outer class variables.

```
01: import javax.swing.*;
02: import java.awt.*;
03: import java.awt.event.*;
04: import java.util.Date;
05: public class EventWithInnerClass extends JFrame {
06:
      JButton b1;
07:
      JLabel lbl;
08:
      public EventWithInnerClass() {
       super("Event with Inner Class");
09:
       lbl = new JLabel();
10:
       lbl.setHorizontalAlignment(JLabel.CENTER);
11:
12:
       b1 = new JButton("Click Here");
       b1.addActionListener(new ActionEventHandler());
13:
14:
       Container c = getContentPane();
       c.add(lbl, BorderLayout.PAGE START);
15:
       c.add(b1, BorderLayout.PAGE END);
16:
       setDefaultCloseOperation
17:
18:
                        (WindowConstants.EXIT ON CLOSE);
       setSize(300,200);
19:
20:
21:
      // inner class
      class ActionEventHandler implements ActionListener {
22:
        public void actionPerformed(ActionEvent evt) {
23:
24:
          lbl.setText (new Date().toString());
25:
      } // end of inner class
26:
27:
      public static void main(String args[]) {
28:
        new EventWithInnerClass().setVisible(true);
      }
29:
30:
```

Using anonymous inner class as event listener

As inner class used to handle event needs only one object and no more, it is possible to create inner class with no name (Anonymous inner class) and create an object at the time of defining the class.

```
01: import javax.swing.*;
02: import java.awt.*;
03: import java.awt.event.*;
04: import java.util.Date;
05: public class EventWithAIC extends JFrame {
06:
        JButton b1:
07:
        JLabel lbl;
08:
        public EventWithAIC() {
          super("Event with Anonymous Inner Class");
09:
10:
          lbl = new JLabel();
11:
          lbl.setHorizontalAlignment(JLabel.CENTER);
          b1 = new JButton("Click Here");
12:
13:
          b1.addActionListener(new ActionListener() {
14:
             public void actionPerformed(ActionEvent evt) {
15:
                 lbl.setText(new Date().toString());
16:
17:
             }
          });
18:
19:
          Container c = getContentPane();
20:
          c.add(lbl, BorderLayout.PAGE START);
          c.add(b1, BorderLayout.PAGE END);
21:
22:
23:
          setDefaultCloseOperation
                 (WindowConstants.EXIT ON CLOSE);
24:
          setSize(300,200);
25:
26:
        public static void main(String args[]) {
27:
          new EventWithAIC().setVisible(true);
28:
29:
        }
30: }
```

Event Handling with Lambda Expressions

Starting from Java 8, we can handle events that are part of Functional Interface like *ActionListener* using Lambda expressions. Event handling in the previous program can be replaced with Lambda expression.

```
01: import java.awt.*;
02: import java.util.Date;
03: import javax.swing.*;
04: public class ActionEventWithLambda extends JFrame {
05:
        JButton b1;
06:
        JLabel lbl;
07:
08:
        public ActionEventWithLambda() {
            super("ActionEvent with Lambda");
09:
            lbl = new JLabel();
10:
            lbl.setHorizontalAlignment(JLabel.CENTER);
11:
12:
            b1 = new JButton("Show Date and Time");
13:
            b1.addActionListener
                 (e -> lbl.setText(new Date().toString()));
14:
            Container c = getContentPane();
15:
            c.add(lbl, BorderLayout.PAGE START);
16:
            c.add(b1, BorderLayout.PAGE END);
17:
18:
            setDefaultCloseOperation
19:
                  (WindowConstants.EXIT ON CLOSE);
            setSize(300, 200);
20:
21:
        }
        public static void main(String args[]) {
22:
            new ActionEventWithLambda().setVisible(true);
23:
        }
24:
25: }
```

Show Date and Time	

Color Class

It represents a single color. It creates a color with the given portions of red, green and blue.

The following are the static variables (constants) of **Color** type defined in **Color** class:

black, blue, cyan, darkGray, gray, green, lightGray, magenta, orange, pink, red, white, yellow.

The following constructor can be used to create a new color by using given amount of red, green and blue.

Color (int red, int green, int blue)

The following are important methods of Color class.

Method	Meaning
int getBlue()	Returns the blue component.
int getGreen()	Returns the green component.
int getRed()	Returns the red component.

JLabel Class

This is used to display unselectable text or image.

```
JLabel(Icon)
JLabel(String)
JLabel(String s, Icon I, int align)
```

The align parameter could be either JLabel.LEFT or JLabel.RIGHT or JLabel.CENTER constants.

Method	Meaning
String getText()	Returns or sets the text of the label.
void setText(String)	
Icon getIcon()	Gets or sets the image displayed by the label.
void setIcon(Icon)	
void setHorizontalAlignment	Sets or gets where content in the label is to be
(int align)	displayed.
int getHorizontalAlignment()	

JTextField Class

It provides a single-line textbox, which allows user to enter and edit text.

```
JTextField(int cols)
JTextField(String s)
JTextField(String s, int cols)
```

Parameter *cols* is used to specify the number of columns in the text field. It is used to calculate the preferred width of text field. The following are other important methods of text field.

Method	Meaning
String getText()	Sets or gets text displayed in the text field.
void setText(String)	
void setEditable(boolean)	Sets or gets whether user can edit text in the text
boolean isEditable()	field.
int getColumns()	Sets or gets number of columns displayed by text
void setColumns(int)	field. This is used to calculate preferred size of text
	box.
void selectAll()	Selects all characters in the text field.

ActionEvent occurs when user presses "enter" key in the text field. This event can be handled using **addActionListener** (**ActionListener**) method.

JPasswordField Class

This class is used to provide a textbox for passwords. It hides the characters entered by the user. It extends **JTextField**.

```
JPasswordField()
JPasswordField(int cols)
JPasswordField(String s, int cols)
```

Other useful methods of password field are given below.

Method	Meaning
void setEchoChar(char)	Sets or gets character that is displayed instead of the
char getEchoChar()	actual character entered by user.
char[] getPassword()	Returns password entered by user.

JTextArea Class

It displays multiple lines of text and allows user to edit text. You can customize by specifying how text is wrapped. It extends **JTextComponent** class.

```
JTextArea()
JTextArea(String)
JTextArea(String, int rows, int columns)
JTextArea(int rows, int columns)
```

The following are the important methods of text area.

Method	Meaning
void setColumns(int)	Sets or gets the number of columns displayed by the
int getColumns()	text area.
void setRows(int)	Sets or gets the number of rows displayed by the
int getRows()	text area.
int setLineWrap (boolean)	Sets whether lines are wrapped if they are too long
	to fit within the allocated width. Default value is
	false.
int setWrapStyleWord	Sets whether lines can be wrapped at white space
(boolean)	(word boundaries) or at any character. Default value
	is false.
void append(String)	Adds the specified text to the end of the text area.
void insert(String, int)	Inserts the specified text at the specified position.
void replaceRange (String,	Replaces the text between the indicated positions
int, int)	with the specified string.
int getLineCount()	Returns number of lines.

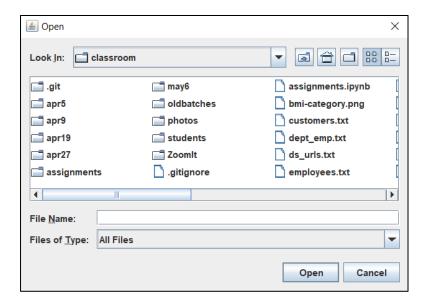

304

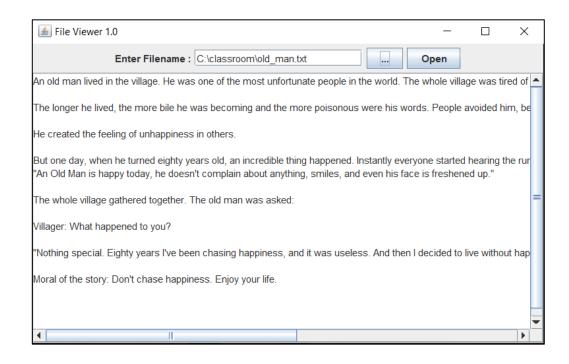

JButton Class

It provides the functionality of a push button and displays text or icon or both. It extends **AbstractButton** class, which extends **JComponent**.

JButton(Icon) JButton(String) JButton(String,<u>Icon)</u>

Method	Meaning
String getText() void setText(String)	Gets or sets text of the button.
Icon getIcon() void setIcon(Icon)	Gets or sets image of the button.
void addActionListener (ActionListener) void removeActionListener (ActionListener)	Adds or removes action listener used to handle action event of the button.

               Path path = Path.of(tfFilename.getText());
55:
               // Java 12 readString(Path) of Files
56:
               taContents.setText(Files.readString(path));
57:
            } catch (Exception ex) {
58:
59:
               taContents.setText(ex.getMessage());
            }
60:
61:
      }
62:
```

JCheckBox Class

It provides the functionality of a check box. It extends **JToggleButton**, which extends **AbstractButton** class.

```
JCheckBox(Icon icon)
JCheckBox(String text)
JCheckBox(String text, boolean selected)
JCheckBox(Icon icon, boolean selected)
JCheckBox(String text, Icon icon)
```

Method	Meaning
boolean isSelected()	Returns true if check box is selected.
void setSelected	Sets the state of check box either to checked or
(boolean)	unchecked.

Check box generates item event when user turns on or off the checkbox. You can add an item listener using addItemListener() method.

ItemListener interface contains itemStateChanged(ItemEvent) method.

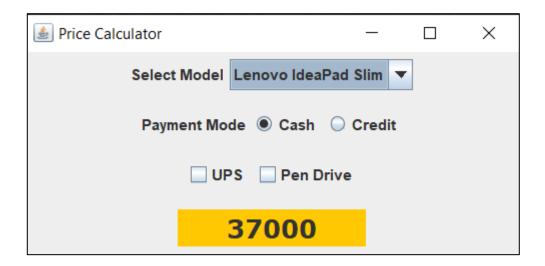

JRadioButton Class

It represents a radio button. It extends **JToggleButton**. Radio buttons are to be grouped using **ButtonGroup** class to form mutually exclusive radio buttons group.

```
JRadioButton(String text)
JRadioButton(String text, boolean selected)
JRadioButton(Icon image)
JRadioButton(Icon image, boolean selected)
JRadioButton(String text, Icon image)
```

Method **isSelected()** and **setSelected()** may be used with radio button for the same purpose as **JCheckBox**.

NOTE: ButtonGroup class is used to group radio buttons so that only one button in the group can be selected. Method **add()** is used to add objects of **JRadioButton** to button group.

JComboBox class

It provides a drop-down list box cum a text box. Combo box combines the functionality of listbox and textbox.

```
JComboBox()
JComboBox(Object [])
JComboBox(Vector v)
```

Method	Meaning
void addItem(Object)	Adds an item to combo box. Insert method
void insertItemAt(Object, int)	places item at the given position.
Object getItemAt(int)	Gets an item from combo box.
Object getSelectedItem()	
int getSelectedIndex()	
int getItemCount()	Returns the number of items.
boolean isEditable()	Determines whether combo box is editable.
void setEditable(boolean)	
void removeltemAt(int index)	Removes all items or the specified items from
void removeAllItems()	combo box.
void removeItem(Object)	
void setSelectedIndex(int)	Selects the item with the given index or value.
void setSelectedItem(Object)

```
private void displayPrice() {
55:
56:
        int prices[] = {37000,38000,40000};
        int amount;
57:
58:
          amount=prices[cmbModels.getSelectedIndex()];
59:
          if (rbCredit.isSelected())
60:
                   amount *= 1.08; // 8% interest
61:
          if (cbUps.isSelected())
62:
63:
                   amount += 2000;
          if (cbPendrive.isSelected())
64:
65:
                   amount += 500;
          lblAmount.setText(String.valueOf(amount));
66:
67:
        public static void main(String args[]) {
68:
            new PriceCalculator().setVisible(true);
69:
70:
        }
71:
```

314

JScrollPane Class

It represents scroll pane in Swing. It provides horizontal and vertical scrollbars optionally. Every control that needs scrolling functionality must be placed in **JScrollPane** and then JScrollPane is placed in the container.

JScrollPane(component, vspolicy, hspolicy)

Component is the component that is to be displayed with scroll bars.

Vspolicy may be any of the following:

```
JScrollPane.VERTICAL_SCROLLBAR_AS_NEEDED
JScrollPane.VERTICAL_SCROLLBAR_NEVER
JScrollPane.VERTICAL SCROLLBAR ALWAYS
```

Hspolicy may be any of the following:

```
JScrollpane.HORIZONTAL_SCROLLBAR_AS_NEEDED
JScrollpane.HORIZONTAL_SCROLLBAR_NEVER
JScrollpane.HORIZONTAL SCROLLBAR ALWAYS
```

JList Class

- ☐ It represents a list box. It takes data from a Vector or an array of Objects.
- ☐ It allows single or multi-selection.
- ☐ The items in the list are managed by list model and selection is managed by list selection model.

```
JList()
JList(ListModel)
JList(Vector)
JList(Object[])
```

ListModel can be an instance of **DefaultListModel**, which is providing methods of old Vector class.

Method	Meaning
void clearSelection()	Unselects all selected items.
int getSelectedIndex()	Returns index of the selected item.
<pre>int[] getSelectedIndices()</pre>	Returns indexes of all selected items.
Object getSelectedValue()	Returns selected value.
Object[] getSeletedValues()	Returns all selected values.
boolean isSelectedIndex(int)	Returns true if item with the given index is
	selected.
void setSelectedIndex(int)	Selects the items with the given index(es).
<pre>void setSelectedIndices(int[])</pre>	
void setSelectedValue(Object	Selects the specified value. shouldscroll specifies
item, boolean shouldscroll)	whether list should scroll to show the selected
	item.
Void setListData(Vector)	Sets the data of the list box.
<pre>void setListData(Object [])</pre>	
void setModel(ListModel)	Sets or gets current list model.
ListModel getModel()	

int getFirstVisibleIndex()	Returns first and last visible items' indexes.
int getLastVisibleIndex()	
int getSelectionMode()	Gets or sets selection mode. It may be
void setSelectionMode(int)	SINGLE_SELECTION,
	SINGLE_INTERVAL_SELECTION,
	MULTIPLE_INTERVAL_SELECTION (default).

JOptionPane Class

It contains a set of standard dialog boxes. It provides static methods that are used to invoke standard dialog boxes. It also allows you to customize dialog boxes to specify title and text.

The following are static methods provided by **JOptionPane** to display different dialog boxes.

void showMessageDialog(Component parent, Object Message,
String title, int MessageType);

MessageType may be one of the constants in JOptionPane class:

ERROR_MESSAGE, INFORMATION_MESSAGE, WARNING_MESSAGE QUESTION_MESSAGE, PLAIN_MESSAGE

int showConfirmDialog(Component parent, Object Message, String title, int OptionType, int MessageType)

OptionType may be either YES_NO_OPTION or YES_NO_CANCEL_OPTION. Return value is equal to YES_OPTION, NO_OPTION or CANCEL_OPTION.

String showInputDialog(Component parent, Object message,
String title, int MessageType)

String **showInputDialog**(Component parent, Object message, String title, int messageType, int Icon, Object [] options, Object defaultvalue)

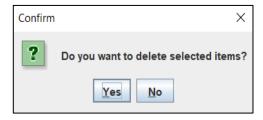

```
01: import java.awt.BorderLayout;

```

Timer Class

It is used to generate events at regular interval. It generates action event at the given interval.

Timer(int delay, ActionListener listener)

Parameter *delay* is the interval at which action event occurs. It is specified in milliseconds.

Method	Meaning
void start()	Starts firing event at the given interval.
void stop()	Stops firing events.
void restart()	Restarts firing events.
void setDelay(int)	Changes the interval.

```
01: import java.awt.Font;
02: import java.time.LocalTime;
